2.1. Sheaves.

2021.7.8 zyn

Exercise 2.1.1. Let A be an abelian group, and define the constant presheaf associated to A on the topological space X to be the presheaf $U \mapsto A$ for all $U \neq \emptyset$, with restriction maps the identity. Show that the constant sheaf \mathcal{A} defined in the text is the sheaf associated to this presheaf.

Proof. The sheafification is defined by the universal property in [Har77], thus we prove that \mathcal{A} satisfies the universal property. Let \mathcal{G} be any sheaf and let \mathcal{F} be the constant presheaf, and suppose $\varphi : \mathcal{F} \rightarrow \mathcal{G}$. Let $f \in \mathcal{A}(U)$. Write $U = \coprod V_\alpha$ with V_α the connected components of U so $f(V_\alpha) = a_\alpha \in A$. Then we get $b_\alpha = \varphi(V_\alpha)(a_\alpha)$ since $\mathcal{F}(U) = A$ for any U , and since \mathcal{G} is a sheaf we obtain $b \in \mathcal{G}(U)$. We define $\psi : \mathcal{A} \rightarrow \mathcal{G}$ by $\psi(U)(f) = b$. \square

Exercise 2.1.2. (a) For any morphism of sheaves $\varphi : \mathcal{F} \rightarrow \mathcal{G}$, shows that for each point P , $(\ker \varphi)_P = \ker(\varphi_P)$ and $(\operatorname{im} \varphi)_P = \operatorname{im}(\varphi_P)$.

(b) Show that φ is injective (respectively, surjective) if and only if the induced map on the stalks φ_P is injective (respectively, surjective) for all P .

(c) Show that a sequence of $\dots \mathcal{F}^{i-1} \xrightarrow{\varphi^{i-1}} \mathcal{F}^i \xrightarrow{\varphi^i} \mathcal{F}^{i+1} \longrightarrow \dots$ sheaves and morphisms is exact if and only if for each $P \in X$ the corresponding sequence of stalks is exact as a sequence of abelian groups.

Proof. (a) Actually it's the only difficult part of the exercise. Stalk can be regarded as a direct limit, i.e. $(\ker \varphi)_P = \varinjlim (\ker \varphi)(U) = \varinjlim \ker \varphi(U)$, which is a subgroup of \mathcal{F}_P , so we show equality inside \mathcal{F}_P . For $x \in (\ker \varphi)_P$ pick (U, y) representing x , with $y \in \ker \varphi(U)$. Then the image of y in \mathcal{F}_P , i.e. x , is mapped to zero by φ_P . Conversely, if $x \in \ker(\varphi_P)$ there exist (U, y) with $y \in \mathcal{F}(U)$ and $\varphi(U)(y) = 0$ so $x \in (\ker \varphi)_P$.

For $\text{im } \varphi$ one proceeds similarly, noting only that $(\text{im } \varphi)_P = \varinjlim \text{im } \varphi(U)$ since the presheaf “ $\text{im } \varphi$ ” and the sheaf $\text{im } \varphi$ have the same stalks at every point (and the commutivity is true for presheaf).

(b) φ is injective (resp. surjective) iff $(\ker \varphi)_P = 0$ (resp. $(\text{im } \varphi)_P = \mathcal{G}_P$) for all P . By a), this holds iff $\ker \varphi_P = 0$ (resp. $\text{im } \varphi_P = \mathcal{G}_P$) for all P , that is, iff φ_P is inj. (resp. surj.).

(c) By (a), We have $\text{im } \varphi^{i-1} = \ker \varphi^i$ iff $\text{im } \varphi_P^{i-1} = (\text{im } \varphi^{i-1})_P = (\ker \varphi^i)_P = \ker \varphi_P^i$. \square

2021.7.11 hyx

Exercise 2.1.3. (a) Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a morphism of sheaves on X . Show that φ is surjective if and only if the following conditions holds: for every open set $U \subseteq X$, and for every $s \in \mathcal{G}(U)$, there is a covering $\{U_i\}$ of U , and there are elements $t_i \in \mathcal{F}(U_i)$, such that $\varphi(U_i)(t_i) = s|_{U_i}$ for all i .

(b) Give an example of a surjective morphism of sheaves $\varphi : \mathcal{F} \rightarrow \mathcal{G}$, and an open set U such that $\varphi(U) : \mathcal{F}(U) \rightarrow \mathcal{G}(U)$ is not surjective.

Proof. (a) (1) Assume that φ is surjective. Thus we have $\text{im } \varphi = \mathcal{G}$. By the definition of sheafification in Proposition-Definition 2.1.2*, for any open subset $U \subseteq X$, $\mathcal{G}(U)$ consists of functions $s : U \rightarrow \bigcup_{p \in U} \text{im } \varphi_p$ satisfying: for each $p \in U$, $s(p) \in \text{im } \varphi_p$, and there exists an open subset V_p and $a \in \text{im } \varphi(V_p)$ with $p \in V_p \subseteq U$, such that $s(q) = a_q$ for any $q \in V_p$. Choose $t \in \mathcal{F}(V_p)$ with $s(V_p)(t) = a$. Let \mathcal{M} be the presheaf sending U to $\text{im } \varphi(U)$ and factor φ as

$$\mathcal{F} \xrightarrow{\tilde{\varphi}} \mathcal{M} \xrightarrow{\theta} \mathcal{G}.$$

Then we have $\varphi(V_p)(t) = \theta(V_p) \circ \tilde{\varphi}(V_p)(t) = \theta(V_p)(a) = s|_{V_p}$. Using the notations t_i and U_i instead of t and V_p respectively, we get half part of the conclusion.

(2) Assume the condition is satisfied. By the universal property of sheafification, factor φ as

$$\mathcal{F} \xrightarrow{\tilde{\varphi}} \mathcal{M} \xrightarrow{\theta} \text{im } \varphi \xrightarrow{\psi} \mathcal{G}.$$

It suffices to show that ψ is an isomorphism. Define $\alpha : \mathcal{G} \rightarrow \text{im } \varphi$: for any open subset $U \subseteq X$,

$$\alpha(U) : \mathcal{G}(U) \longrightarrow (\text{im } \varphi)(U), \quad s \longmapsto (f : p \rightarrow s_p).$$

For any $p \in U$, p lies in U_i for some i . Then there exists $t_i \in \mathcal{F}(U_i)$ such that $s_i = \varphi(U_i)(t_i) = s|_{U_i} \in \mathcal{M}(U_i)$. Thus for each $q \in U_i$, $f(q) = s_q = (s_i)_q$. Hence $f \in (\text{im } \varphi)(U)$ and α is well-defined. It is easy to verify that $\alpha \circ \psi \circ \theta = \theta$. Then by the universal property,

$$(2.1.3.1) \quad \alpha \circ \psi = \text{id}_{\mathcal{F}}.$$

On the other hand, for $s \in \ker \alpha(U)$, $s_p = 0$ for all $p \in U$. Then we may get $s = 0$ with some simple discussion, and hence $\ker \alpha(U) = 0$. Thus α is injective. Together with the equality $\alpha \circ \psi \circ \alpha = \alpha$ which follows (2.1.3.1), we have

$$(2.1.3.2) \quad \psi \circ \alpha = \text{id}_{\mathcal{G}}.$$

With the equalities (2.1.3.1) and (2.1.3.2), we may conclude that ψ is an isomorphism.

(b) Let $X = \mathbb{R}$, $\mathcal{F}(U) = \mathcal{G}(U) = \{\text{Monotone increasing continuous functions on } U\}$, and $\varphi : \mathcal{F}(U) \rightarrow \mathcal{G}(U)$, such that

$$\varphi(f) = f\chi_{\{|f| \leq 1\}} + f(1)\chi_{\{f \geq 1\}} + f(-1)\chi_{\{f \leq -1\}},$$

*Unless otherwise indicated, Proposition, Theorem, Corollary, Lemma or Ex. appearing in this note stands for the corresponding one in [Har77]. For instance, Proposition 1.3.5 stands for Proposition 3.5 of Chapter 1 in [Har77].

then

$$\text{im } \varphi(U) = \{\text{Monotone increasing continuous bounded functions on } U\},$$

but $(\text{im } \varphi)(U) = \mathcal{G}(U)$. \square

Exercise 2.1.4. (a) Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a morphism of presheaves such that $\varphi(U) : \mathcal{F}(U) \rightarrow \mathcal{G}(U)$ is injective for each U . Show that the induced map $\varphi^+ : \mathcal{F}^+ \rightarrow \mathcal{G}^+$ of associated sheaves is injective.

(b) Use part (a) to show that if $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ is a morphism of sheaves, then $\text{im } \varphi$ can be naturally identified with a subsheaf of \mathcal{G} , as mentioned in the text.

Proof. (a) Since $\varphi(U) : \mathcal{F}(U) \rightarrow \mathcal{G}(U)$ is injective, then $\varphi_p : \mathcal{F}_p \rightarrow \mathcal{G}_p$ is injective. Notice that $\mathcal{F}_p^+ = \mathcal{F}_p$, $\mathcal{G}_p^+ = \mathcal{F}_p$, and $\varphi_p = \varphi_p^+$, so φ_p^+ is injective. By Ex. 2.1.2 (b) φ^+ is injective.

(b) Let \mathcal{M} be the presheaf given by $U \mapsto \text{im } \varphi(U)$. The inclusion map $i : \mathcal{M} \rightarrow \mathcal{G}$ is injective. By (a), $i^+ : \text{im } \varphi \rightarrow \mathcal{G}^+ = \mathcal{G}$ is injective. \square

2021.7.12 wxj

Exercise 2.1.5. Show that a morphism of sheaves is an isomorphism iff it is injective and surjective.

Proof. By Proposition 2.1.1, φ is an isomorphism iff the induced map on the stalk φ_P is an isomorphism for any $P \in X$.

By Ex. 2.1.2 (b), φ is injective and surjective iff the induced map on the stalk φ_P is injective and surjective, i.e. φ_P is an isomorphism, for all $P \in X$.

With the discussion above, we can conclude that φ isomorphism iff it is injective and surjective. \square

Exercise 2.1.6. (a) Let \mathcal{F}' be a subsheaf of a sheaf \mathcal{F} . Show that the natural map of \mathcal{F} to the quotient sheaf \mathcal{F}/\mathcal{F}' is surjective, and has kernel \mathcal{F}' . Thus there is an exact sequence $0 \rightarrow \mathcal{F}' \rightarrow \mathcal{F} \rightarrow \mathcal{F}/\mathcal{F}' \rightarrow 0$.

(b) Conversely, if $0 \rightarrow \mathcal{F}' \rightarrow \mathcal{F} \rightarrow \mathcal{F}'' \rightarrow 0$ is an exact sequence, show that \mathcal{F}' is isomorphic to a subsheaf of \mathcal{F} , and that \mathcal{F}'' is isomorphic to the quotient of \mathcal{F} by this subsheaf.

Proof. (a) By Ex. 2.1.2, it suffices to show that the induced sequence on stalk

$$0 \longrightarrow \mathcal{F}'_P \longrightarrow \mathcal{F}_P \longrightarrow (\mathcal{F}/\mathcal{F}')_P \longrightarrow 0$$

is exact, which follows that $(\mathcal{F}/\mathcal{F}')_P = \mathcal{F}_P/\mathcal{F}'_P$.

(b) If $0 \rightarrow \mathcal{F}' \xrightarrow{\varphi} \mathcal{F} \xrightarrow{\phi} \mathcal{F}'' \rightarrow 0$ is exact. Then $\text{im } \varphi = \ker \phi$. By Ex. 2.1.4 (b) and Ex. 2.1.7 (a), $\mathcal{F}' \simeq \text{im } \varphi$ which can be identified with a subsheaf of \mathcal{F} , and $\mathcal{F}'' = \text{im } \phi \simeq \mathcal{F}/\ker \phi = \mathcal{F}/\text{im } \varphi$. \square

2021.7.13 lc

Exercise 2.1.7. Let $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ be a morphism of sheaves.

(a) Show that $\text{im } \varphi \simeq \mathcal{F}/\ker \varphi$.

(b) Show that $\text{coker } \varphi \simeq \mathcal{G}/\text{im } \varphi$.

Proof. (a) Define the presheaves $\mathcal{F}' : U \mapsto \mathcal{F}(U)/\ker \varphi(U)$ and $\mathcal{G}' : U \mapsto \text{im } \varphi(U)$. Then we have $\mathcal{F}'^+ = \mathcal{F}/\ker \varphi$, $\mathcal{G}'^+ = \text{im } \varphi$, and φ induces the morphism of presheaves $\varphi' : \mathcal{F}' \rightarrow \mathcal{G}'$. Thus we obtain a morphism $\varphi^+ : \mathcal{F}/\ker \varphi \rightarrow \text{im } \varphi$, from the morphism of presheaves

$$\mathcal{F}' \xrightarrow{\varphi'} \mathcal{G}' \longrightarrow \text{im } \varphi$$

by the universal property of the sheaf associated to \mathcal{F}' . For any $x \in X$,

$$\varphi_x^+ : (\mathcal{F} / \ker \varphi)_x = \mathcal{F}_x / \ker \varphi_x \xrightarrow{\varphi_x} \operatorname{im} \varphi_x$$

is an isomorphism. Hence φ^+ is an isomorphism by Proposition 2.1.1.

(b) Similarly, we construct a morphism $\mathcal{G} / \operatorname{im} \varphi \rightarrow \operatorname{coker} \varphi$ applying the universal property of sheafification. Then show this morphism is an isomorphism by Proposition 2.1.1. \square

Exercise 2.1.8. For any open subset $U \subseteq X$, show that the functor $\Gamma(U, -)$ from sheaves to abelian groups is a left exact functor, i.e., if $0 \rightarrow \mathcal{F}' \xrightarrow{\varphi_1} \mathcal{F} \xrightarrow{\varphi_2} \mathcal{F}''$ is an exact sequence of sheaves, then $0 \rightarrow \Gamma(U, \mathcal{F}') \xrightarrow{\varphi_1(U)} \Gamma(U, \mathcal{F}) \xrightarrow{\varphi_2(U)} \Gamma(U, \mathcal{F}'')$ is an exact sequence of abelian groups. The functor $\Gamma(U, -)$ need not to be exact; see (Ex. 2.1.21).

Proof. We only need to show that $\operatorname{im} \varphi_1(U) = \ker \varphi_2(U)$. The exactness of the sequence of sheaves means $\operatorname{im} \varphi_1 = \ker \varphi_2$. Thus $(\operatorname{im} \varphi_1)(U) = \ker \varphi_2(U)$. It suffices to show $\operatorname{im} \varphi_1 = \mathcal{G}$, where \mathcal{G} is a presheaf defined by $V \rightarrow \operatorname{im} \varphi_1(V)$. This is equivalent to that \mathcal{G} is a sheaf.

Assume $\{V_i\}_{i \in I}$ is an open cover of X and $\{y_i\}_{i \in I}$ satisfies $y_i \in \mathcal{G}(V_i)$ and $y_i|_{V_i \cap V_j} = y_j|_{V_i \cap V_j}$ for any $i, j \in I$. Let $x_i = \varphi_1(V_i)^{-1}(y_i) \in \mathcal{F}'(V_i)$. Then

$$\begin{aligned} \varphi_1(V_i \cap V_j)(x_i|_{V_i \cap V_j}) &= \varphi_1(V_i)(x_i)|_{V_i \cap V_j} \\ &= y_i|_{V_i \cap V_j} = y_j|_{V_i \cap V_j} \\ &= \varphi_1(V_i \cap V_j)(x_j|_{V_i \cap V_j}) \end{aligned}$$

for any $i, j \in I$. Hence $x_i|_{V_i \cap V_j} = x_j|_{V_i \cap V_j}$ for any $i, j \in I$, since $\varphi_1(V_i \cap V_j)$ is injective. Thus there exists a unique $x \in \mathcal{F}'(X)$ such that $x|_{V_i} = x_i$ for any $i \in I$. Write $y = \varphi_1(X)(x)$. Then we have

$$y|_{V_i} = \varphi_1(X)(x)|_{V_i} = \varphi_1(V_i)(x_i) = y_i.$$

And the fact that $\varphi_1(X)$ is injective guarantees the uniqueness of $y \in \mathcal{G}(X)$ with $y|_{V_i} = y_i$. Thus \mathcal{G} is a sheaf on X . \square

2021.7.14 ysh

Exercise 2.1.9. Let \mathcal{F} and \mathcal{G} be sheaves on X . Show that the presheaf $U \mapsto \mathcal{F}(U) \oplus \mathcal{G}(U)$ is a sheaf. It is called the direct sum of \mathcal{F} and \mathcal{G} , and is denoted by $\mathcal{F} \oplus \mathcal{G}$. Show that it plays the role of direct sum and of direct product in the category of sheaves of Abelian groups on X .

Proof. Let $\{U_i\}$ be an open cover of U . Given $(s_i, t_i) \in \mathcal{F}(U_i) \oplus \mathcal{G}(U_i)$ such that for all i, j , we have $(s_i, t_i) = (s_j, t_j)$ on $U_i \cap U_j$, then there exists a unique $(s, t) \in \mathcal{F}(U) \oplus \mathcal{G}(U)$ such that $(s, t) = (s_i, t_i)$ on U_i . Namely, we take s to be the gluing of the $\{s_i\}$ and t to be the gluing of the $\{t_i\}$. Hence $\mathcal{F} \oplus \mathcal{G}$ is a sheaf. That $\mathcal{F} \oplus \mathcal{G}$ plays the role of direct sum and direct product in the category of sheaves of Abelian groups on X follows immediately from its description and the fact that direct sum plays this role in the category of Abelian groups. \square

Exercise 2.1.10 (Direct Limit). Let $\{\mathcal{F}_i\}$ be a direct system of sheaves and morphisms on X . We define the direct limit of the system $\{\mathcal{F}_i\}$, denoted $\varinjlim \mathcal{F}_i$, to be the sheaf associated to the presheaf $U \mapsto \varinjlim \mathcal{F}_i(U)$. Show that this is a direct limit in the category of sheaves on X , i.e., that it has the following universal property: given a sheaf \mathcal{G} , and a collection of morphisms $\mathcal{F}_i \rightarrow \mathcal{G}$, compatible with the maps of the direct system, then there exists a unique map $\varinjlim \mathcal{F}_i \rightarrow \mathcal{G}$ such that for each i , the original map $\mathcal{F}_i \rightarrow \mathcal{G}$ is obtained by composing the maps $\mathcal{F}_i \rightarrow \varinjlim \mathcal{F}_i \rightarrow \mathcal{G}$.

Proof. By the universal property of direct limit in the category of Abelian groups, there is a unique morphism of presheaves $(U \mapsto \varinjlim \mathcal{F}_i(U)) \rightarrow \mathcal{G}$ having the desired properties. Now the result follows by using the universal property of sheafification. \square

2021. 7.15 zyn

Exercise 2.1.11. Let $\{\mathcal{F}_i\}$ be a direct system of sheaves on a noetherian topological space X . In this case show that the presheaf $U \mapsto \varinjlim \mathcal{F}_i(U)$ is already a sheaf. In particular, $\Gamma(X, \varinjlim \mathcal{F}_i) = \varinjlim \Gamma(X, \mathcal{F}_i)$.

Exercise 2.1.12 (Inverse limit). Let \mathcal{F}_i be an inverse system of sheaves on X . Show that the presheaf $U \mapsto \varprojlim \mathcal{F}_i(U)$ is a sheaf. It is called the inverse limit of the system \mathcal{F}_i , and is denoted by $\varprojlim \mathcal{F}_i$. Show that it has the universal property of an inverse limit in the category of sheaves.

Proof[†]. I will do the two exercises above together. The inverse limit keeps sheaf since the forgetful functor from sheaves to presheaves is a right adjoint and its left adjoint is the sheafification functor. Left adjoint functor is right exact and commutes with limit, but commutes with colimit under some good condition (for example, Noetherian since we can write U as a finite direct sum). And the universal property is similar to Ex. 2.1.10. In the case we most care, i.e. the sheaf valued in module, the condition of sheaf (the equalizer) is preserved since the direct limit in module category is an exact functor. \square

Exercise 2.1.13 (Étalé Space of a Presheaf). (This exercise is included to establish the connection between our definition of a sheaf and another definition often found in the literature.) Given a presheaf \mathcal{F} on X , we define a topological space $\mathrm{Spé}(\mathcal{F}) = \bigcup_{P \in X} \mathcal{F}_P$. We define a projection map $\pi : \mathrm{Spé}(\mathcal{F}) \rightarrow X$ by sending $s \in \mathcal{F}_P$ to P . For each open set $U \subseteq X$ and each section $s \in \mathcal{F}(U)$, we obtain a map $\bar{s} : U \rightarrow \mathrm{Spé}(\mathcal{F})$ by sending $P \mapsto s_P$, its germ at P . This map has the property that $\pi \circ \bar{s} = \mathrm{id}_U$, in other words, it is a "section" of π on U . We now make $\mathrm{Spé}(\mathcal{F})$ into a topological space by giving it the strongest topology such that all the maps $\bar{s} : U \rightarrow \mathrm{Spé}(\mathcal{F})$ for all U , and all $s \in \mathcal{F}(U)$, are continuous. Now show that the sheaf \mathcal{F}^+ associated to \mathcal{F} can be described as follows: for any open set $U \subseteq X$, $\mathcal{F}^+(U)$ is the set of continuous sections of $\mathrm{Spé}(\mathcal{F})$ over U . In particular, the original presheaf \mathcal{F} is a sheaf if and only if for each U , $\mathcal{F}(U)$ is equal to the set of all continuous sections of $\mathrm{Spé}(\mathcal{F})$ on U .

Proof. Given a presheaf \mathcal{F} , the construction of sheafification in [Har77] (see Proposition-Definition 2.1.2) is:

For any open subset $U \subseteq X$, $\mathcal{F}^+(U)$ consists of all $s : (1) U \rightarrow \bigcup_{P \in U} \mathcal{F}_P$, for each $P \in U$, $s(P) \in \mathcal{F}_P$; (2) for each $P \in U$, there is a neighborhood V of P , contained in U , and an element $t \in \mathcal{F}(V)$, such that for all $Q \in V$, the germ t_Q of t at Q is equal to $s(P)$.

The definition of the exercise is: \mathcal{F}^+ consists of all continuous $s \in \mathrm{Spé}(\mathcal{F})$.

If the definition of [Har77] holds, condition (1) implies it's a section, and condition (2) implies that locally s coincides with a section of \mathcal{F} , as continuous is a local property, result follows from the definition of the topology defined on $\mathrm{Spé}(\mathcal{F})$.

Conversely, given a continuous section, (1) holds obviously, and if the condition of [Har77] fails, then we can find a sequence of points x_i converges to p , and a sequences of section s_i of \mathcal{F} all take value with $s(p)$ at p , (which is continuous by the definition of the topology of $\mathrm{Spé}(\mathcal{F})$), then comes a contradiction. \square

[†]This symbol means that the proof is given in the language of homological algebra, which is not essential for solving this exercise, but is definitely necessary for further study. See [Wei94].

2021. 7.16 hyx

Exercise 2.1.14 (Support). Let \mathcal{F} be a sheaf on X , and let $s \in \mathcal{F}(U)$ be a section over an open set U . The Support of s , denoted $\text{Supp } s$, is defined to be $\{P \in U \mid s_P \neq 0\}$, where s_P denotes the germ of s in the stalk \mathcal{F}_P . Show that $\text{Supp } s$ is a closed subset of U . We define the support of \mathcal{F} , $\text{Supp } \mathcal{F}$, to be $\{P \in U \mid \mathcal{F}_P \neq 0\}$. It need not be a closed subset.

Proof. (1) Let $p \in \text{Supp}(s)^c = \{p \in U \mid s_p = 0\}$, then there exists an open subset U_1 with $p \in U_1 \subseteq U$ such that $s|_{U_1} = 0$. So $p \in U_1 \subseteq \text{Supp}(s)^c$, which implies that $\text{Supp}(s)^c$ is open.

(2) Let $X = \mathbb{R}$, and define

$$\mathcal{F}(U) = \{\text{all maps } f \text{ from } U \text{ to } \mathbb{R}, \text{ vanishing near } 0 \text{ if } 0 \in U\}.$$

Then $\mathcal{F}_p \supseteq \mathbb{R}$ for $p \neq 0$, and $\mathcal{F}_0 = 0$. So $\text{Supp } \mathcal{F} = \mathbb{R} - \{0\}$, which is not closed. \square

Exercise 2.1.15 (Sheaf $\mathcal{H}om$). Let \mathcal{F}, \mathcal{G} be sheaves of abelian groups on X . For any open set $U \subseteq X$, show that the set $\text{Hom}(\mathcal{F}|_U, \mathcal{G}|_U)$ of morphisms of the restricted sheaves has a natural structure of abelian group. Show that the presheaf $U \rightarrow \text{Hom}(\mathcal{F}|_U, \mathcal{G}|_U)$ is a sheaf. It is called the sheaf of local morphisms of \mathcal{F} into \mathcal{G} , “sheaf hom” for short, and is denoted $\mathcal{H}om(\mathcal{F}, \mathcal{G})$.

Proof. For $U = \bigcup_{i \in I} U_i$, we denote $\text{Hom}(\mathcal{F}|_U, \mathcal{G}|_U)$ by $\mathcal{H}(U)$.

(1) For $f \in \mathcal{H}(U)$, assume that $f|_{U_i} = 0$. Then $f(V_i)(g) = 0$ for any $V_i \subseteq U_i$ and $g \in \mathcal{F}(V)$. So for any $g \in \mathcal{F}(V)$, $V \in U$, let $V_i = U_i \cap V$. Consequently,

$$f(g)|_{V_i} = f(V_i)(g|_{V_i}) = 0,$$

which implies that $f(V)(g) = 0$. Hence $f = 0$.

(2) For $f_i \in \mathcal{H}(U_i)$ with $f_i|_{U_i \cap U_j} = f_j|_{U_i \cap U_j}$, we define $f : \mathcal{F}|_U \rightarrow \mathcal{G}|_U$ as: For any $g \in \mathcal{F}(V)$, $f_i(g|_{V_i})|_{V_i \cap V_j} = f_j(g|_{V_j})|_{V_i \cap V_j}$, so there exists $s \in \mathcal{G}(V)$, such that $s|_{V_i} = f_i(g|_{V_i})$, and we define $f(g) = s$. It is easy to check that f is a morphism of sheaves, and $f|_{U_i} = f_i$.

By (1) and (2), $U \rightarrow \text{Hom}(\mathcal{F}|_U, \mathcal{G}|_U)$ is a sheaf. \square

2021. 7.17 jil

Exercise 2.1.16 (Flasque Sheaves). A sheaf \mathcal{F} on a topological space X is flasque if for every inclusion $V \subseteq U$ of open sets, the restriction map $\mathcal{F}(U) \rightarrow \mathcal{F}(V)$ is surjective.

(a) Show that a constant sheaf on an irreducible topological space is flasque.

(b) If $0 \rightarrow \mathcal{F}' \rightarrow \mathcal{F} \rightarrow \mathcal{F}'' \rightarrow 0$ is an exact sequence of sheaves, and if \mathcal{F}' is flasque, then for any open set U , the sequence $0 \rightarrow \mathcal{F}'(U) \rightarrow \mathcal{F}(U) \rightarrow \mathcal{F}''(U) \rightarrow 0$ is also exact.

(c) If $0 \rightarrow \mathcal{F}' \rightarrow \mathcal{F} \rightarrow \mathcal{F}'' \rightarrow 0$ is an exact sequence of sheaves, and if \mathcal{F}' and \mathcal{F} are flasque, then \mathcal{F}'' is flasque.

(d) If $f : X \rightarrow Y$ is a continuous map, and if \mathcal{F} is a flasque sheaf on X , then $f_*\mathcal{F}$ is a flasque sheaf on Y .

(e) Let \mathcal{F} be any sheaf on X . We define a new sheaf \mathcal{G} , called the sheaf of discontinuous sections of \mathcal{F} as follows. For each open set $U \subseteq X$, $\mathcal{G}(U)$ is the set of maps $s : U \rightarrow \bigcup_{P \in U} \mathcal{F}_P$ such that for each $P \in U$, $s(P) \in \mathcal{F}_P$. Show that \mathcal{G} is flasque sheaf, and that there is a natural injective morphism of \mathcal{F} to \mathcal{G} .

Proof. (a) For an irreducible topological space, every open set U is connected. So $\mathcal{F}(U)$ consists of constant functions, where the usual restriction gives a surjection.

(b) By Ex. 2.1.8, we only need to show surjectivity, while Ex. 2.1.3 (a) tells us the following fact:

If $0 \rightarrow \mathcal{F}' \xrightarrow{\psi} \mathcal{F} \xrightarrow{\varphi} \mathcal{F}'' \rightarrow 0$ is exact, for all $s \in \mathcal{F}''(U)$, there exists an open cover $\{U_i\}$ of U and $t_i \in \mathcal{F}(U_i)$, such that (short for $\varphi(U_i)(t_i)$), $\varphi(t_i) = s|_{U_i}$ for all i .

Note for $t_i|_{U_{ij}}, t_j|_{U_{ij}} \in \mathcal{F}(U_{ij}) = \mathcal{F}(U_i \cap U_j)$, we have

$$\begin{aligned} \varphi(t_i|_{U_{ij}} - t_j|_{U_{ij}}) &= \varphi(t_i|_{U_{ij}}) - \varphi(t_j|_{U_{ij}}) \\ &= \varphi(t_i)|_{U_{ij}} - \varphi(t_j)|_{U_{ij}} \\ &= s|_{U_{ij}} - s|_{U_{ij}} = 0 \end{aligned}$$

Then the exactness of $0 \rightarrow \mathcal{F}'(U_{ij}) \xrightarrow{\psi} \mathcal{F}(U_{ij}) \xrightarrow{\varphi} \mathcal{F}''(U_{ij})$ suggests that there exists some $r_{ij} \in \mathcal{F}'(U_{ij})$ such that $\psi(r_{ij}) = t_i|_{U_{ij}} - t_j|_{U_{ij}}$. Since \mathcal{F}' is flasque, we may assume $r_{ij} \in \mathcal{F}'(U)$ (then naturally $\psi(r_{ij})$ means $\psi(r_{ij})|_{U_{ij}}$).

We can now define $\tilde{t}_i = t_i, \tilde{t}_j = t_j + \psi(r_{ij}|_{U_j})$. Thus $\tilde{t}_i|_{U_{ij}} = \tilde{t}_j|_{U_{ij}}$ while $\varphi(\tilde{t}_i) = s|_{U_i}, \varphi(\tilde{t}_j) = s|_{U_j}$. Then sheaf prop. (4)[‡] is gonna show its strength.

In order to extend this two-cover technique to infinite-cover, we use Zorn's Lemma in the usual "function extension" sense.

Consider the set of pairs:

$$Z = \{(U_i, t_i) \mid U_i \subseteq U, t_i \in \mathcal{F}(U_i), \varphi(t_i) = s|_{U_i}\}$$

with the following partial order:

$$(U_i, t_i) \leq (U_j, t_j) \text{ if } U_i \subseteq U_j, t_j|_{U_i} = t_i.$$

For any chain $C = \{(U_i, t_i) \mid i \in \lambda\}$, take $V = \bigcup_{i \in \lambda} U_i$, the open cover $\{U_i\}$ and the compatible t_i 's give a unique section $t \in \mathcal{F}(V)$. Since $\varphi(t)|_{U_i} = \varphi(t_i) = s|_{U_i}$, we see $\varphi(t) = s|_V$. So $(V, t) \in Z$ is an upper bound of C . By Zorn's Lemma, there exists a maximal element $(W, r) \in Z$.

To show surjectivity, it suffices to show $W = U$. Suppose the contrary, we take $P \in U - W$. Surjectivity of $\mathcal{F}_P \xrightarrow{\varphi} \mathcal{F}_P''$ gives a preimage r'_P of s_P , leading to a pair (W', r') , where $P \in W' \subseteq U$, $r' \in \mathcal{F}(V)$ such that $\varphi(r') = s|_{W'}$. The technique mentioned before can be used on (W, r) and (W', r') to get a pair $(W \cup W', r'')$, such that $\varphi(r'') = s|_{W \cup W'}$, contrary to the assumption that (W, r) is a maximal of Z .

(c) \mathcal{F}' is flasque, so the natural transformations (morphisms) give rise to a two-row row-exact diagram w.r.t $V \subseteq U$. Then since \mathcal{F} is flasque, the problems is solved by five lemma immediately.

(d) For open subsets $V \subseteq U$, $f^{-1}(V) \subseteq f^{-1}(U)$, so the restriction

$$f_*\mathcal{F}(U) = \mathcal{F}(f^{-1}(U)) \longrightarrow \mathcal{F}(f^{-1}(V)) = f_*\mathcal{F}(V)$$

is surjective.

(e) \mathcal{G} is a sheaf for sure. For any open subset $V \subseteq U$, taking 0 outside V gives a preimage for for all $s \in \mathcal{G}(V)$. Define $\varphi : \mathcal{F} \rightarrow \mathcal{G}$ by setting $\varphi(U) : \mathcal{F}(U) \rightarrow \mathcal{G}(U)$, $t \mapsto (s : P \mapsto t_P)$. For $t \in \mathcal{F}(U)$, $P \in V \subseteq U$, $t_P = (t|_V)_P$, since they coincide on V . Then the identification of $S|_V : P \mapsto t_P$ and $S|_V : P \mapsto (t|_V)_P$ shows φ is a morphism. φ is injective since sheaf prop. (3) suggests $\varphi(U)$ is injective for all U . \square

Exercise 2.1.17 (Skyscraper Sheaves). Let X be a topological space, let P be a point, and let A be an abelian group. Define a sheaf $i_P(A)$ on X as follows: $i_P(A)(U) = A$ if $P \in U$, 0 otherwise. Verify that the stalk of $i_P(A)$ is A at every point $Q \in \{P\}^-$, and 0 elsewhere, where $\{P\}^-$ denotes the closure of the set consisting of the point P . Hence the name "skyscraper sheaf". Show that this

[‡]See [Har77, P. 61] for sheaf prop. (1)(2)(3) and (4).

sheaf could also be described as $i_*(A)$, where A denotes the constant sheaf A on the closed subspace $\{P\}^-$, and $i : \{P\}^- \rightarrow X$ is the inclusion.

Proof. (1) The condition $Q \in \{P\}^-$ means that for any open subset $V_Q \ni Q$, we have $P \in V_Q$. So $i_P(A)(V_Q) = A$, then $i_P(A)_Q = A$. For $Q \notin \{P\}^-$, there exists an open subset $U \ni Q$ with $P \notin U$, then for any open subset V with $Q \in V \subseteq U$, $i_P(A)(V) = 0$, so $i_P(A)_Q = 0$.

(2) By Ex. 1.1.6, $\{P\}^-$ is irreducible. If $p \in U$, then

$$i_*(A)(U) = A(i^{-1}(U)) = A(U \cap \{P\}^-) = A.$$

Otherwise, $i_*(A)(U) = A(\emptyset) = 0$. □

2021.7.19 wxj

Exercise 2.1.18 (Adjoint Property of f^{-1}). Let $f : X \rightarrow Y$ be a continuous map of topological spaces. Show that for any sheaf \mathcal{F} on X there is a natural map $f^{-1}f_*\mathcal{F} \rightarrow \mathcal{F}$, and for any sheaf \mathcal{G} on Y there is a natural map $\mathcal{G} \rightarrow f_*f^{-1}\mathcal{G}$. Use these maps to show that there is a natural bijection of sets, for any sheaves \mathcal{F} on X and \mathcal{G} on Y , $\text{Hom}_X(f^{-1}\mathcal{G}, \mathcal{F}) = \text{Hom}_Y(\mathcal{G}, f_*\mathcal{F})$.

Hence we say that f^{-1} is a left adjoint of f_* , and that f_* is a right adjoint of f^{-1} .

Proof. Throughout this exercise, we assume that W and V are open subsets of X and Y respectively.

Define the presheaf

$$\mathcal{F}' : W \longmapsto \varinjlim_{f(W) \subseteq U} f_*\mathcal{F}(U) = \varinjlim_{W \subseteq f^{-1}(U)} \mathcal{F}(f^{-1}(U)) ,$$

and the natural inclusion to the sheaf associated to it

$$\theta_1 : \mathcal{F}' \longrightarrow f^{-1}f_*\mathcal{F} .$$

For any open subset $W \subseteq X$, $\mathcal{F}(W) = \varinjlim_{W \subseteq U} \mathcal{F}(U)$, together with the universal property of direct limits, which implies a natural map $r(W) : \mathcal{F}'(W) \rightarrow \mathcal{F}(W)$. Since $f^{-1}f_*\mathcal{F}$ is the sheaf associated to \mathcal{F}' , we get the natural map

$$\alpha : f^{-1}f_*\mathcal{F} \longrightarrow \mathcal{F}$$

by the universal property.

Define

$$\mathcal{G}' : V \longmapsto \varinjlim_{f(V) \subseteq U} \mathcal{G}(U) \quad \text{and} \quad \theta_2 : \mathcal{G}' \longrightarrow f^{-1}\mathcal{G}$$

where θ_2 is the natural inclusion. Since for any open subset $V \subseteq Y$,

$$\mathcal{G}'(f^{-1}(V)) = \varinjlim_{f(f^{-1}(V)) \subseteq U} \mathcal{G}(U) \quad \text{and} \quad f(f^{-1}(V)) \subseteq V,$$

we get a map $\iota(V) : \mathcal{G}(V) \rightarrow \mathcal{G}'(f^{-1}(V))$. Then we obtain the natural map $\beta : \mathcal{G} \rightarrow f_*f^{-1}\mathcal{G}$ by the following sequence:

$$\beta(V) : \mathcal{G}(V) \xrightarrow{\iota(V)} \mathcal{G}'(f^{-1}(V)) \xrightarrow{\theta_2(f^{-1}(V))} f^{-1}\mathcal{G}(f^{-1}(V)) = f_*f^{-1}\mathcal{G}(V) .$$

Then we define $\varphi : \text{Hom}_X(f^{-1}\mathcal{G}, \mathcal{F}) \rightarrow \text{Hom}_Y(\mathcal{G}, f_*\mathcal{F})$. Let $\mu \in \text{Hom}_X(f^{-1}\mathcal{G}, \mathcal{F})$. Then define $\varphi(\mu) : \mathcal{G} \rightarrow f_*\mathcal{F}$ for any open subset $V \subseteq Y$ as following:

$$\varphi(\mu)(V) : \mathcal{G}(V) \xrightarrow{\beta(V)} f_*f^{-1}\mathcal{G}(V) = f^{-1}\mathcal{G}(f^{-1}(V)) \xrightarrow{\mu(f^{-1}(V))} \mathcal{F}(f^{-1}(V)) = f_*\mathcal{F}(V)$$

Then define $\psi : \text{Hom}_Y(\mathcal{G}, f_*\mathcal{F}) \rightarrow \text{Hom}_X(f^{-1}\mathcal{G}, \mathcal{F})$. Assume that $\xi \in \text{Hom}_Y(\mathcal{G}, f_*\mathcal{F})$ and W is an open subset of X . The morphism ξ induces a natural map

$$\mathcal{G}' \xrightarrow{\xi'} \mathcal{F}' \xrightarrow{\theta_1} f^{-1}f_*\mathcal{F}.$$

Then applying the universal property of the sheaf associated to \mathcal{G}' , we obtain a natural map $f^{-1}\xi : f^{-1}\mathcal{G} \rightarrow f^{-1}f_*\mathcal{F}$. Then we can define

$$\psi(\xi) = \alpha \circ f^{-1}\xi.$$

Finally, we need to show that the two maps defined above are invertible to each other.

Let $\mu \in \text{Hom}_X(f^{-1}\mathcal{G}, \mathcal{F})$. Write $\varepsilon = \varphi(\mu) \in \text{Hom}_Y(\mathcal{G}, f_*\mathcal{F})$. Then

$$\begin{aligned} \varepsilon(V) &= \varphi(\mu)(V) = \mu(f^{-1}(V)) \circ \beta(V) \\ &= \mu(f^{-1}(V)) \circ \theta_2(f^{-1}(V)) \circ \iota(V). \end{aligned}$$

With this equality, we calculate $\psi(\varepsilon)$ as following:

$$\begin{array}{ccccccc} & & & \psi(\varepsilon) & & & \\ & & & \curvearrowright & & & \\ \mathcal{G}' & \xrightarrow{\theta_2} & f^{-1}\mathcal{G} & \xrightarrow{f^{-1}\varepsilon} & f^{-1}f_*\mathcal{F} & \xrightarrow{\alpha} & \mathcal{F} \\ & \searrow \varepsilon' & & \nearrow \theta_1 & \nearrow r & & \\ & & \mathcal{F}' & & & & \end{array}$$

Applying the universal property of the sheafification of \mathcal{G}' , we only need to calculate $r \circ \varepsilon'$:

$$\begin{aligned} (r \circ \varepsilon')(W) &= r(W) \circ \varepsilon'(W) = r(W) \circ \varinjlim_{f(W) \subseteq U} \varepsilon(U) \\ &= r(W) \circ \varinjlim_{f(W) \subseteq U} ((\mu \circ \theta_2)(f^{-1}(U)) \circ \iota(U)) \\ (2.1.18.1) \quad &= (r(W) \circ \varinjlim_{f(W) \subseteq U} (\mu \circ \theta_2)(f^{-1}(U))) \circ \varinjlim_{f(W) \subseteq U} \iota(U) \\ (2.1.18.2) \quad &= \varinjlim_{W \subseteq U} (\mu \circ \theta_2)(U) \circ \text{id}_{\mathcal{G}'(W)} = (\mu \circ \theta_2)(W). \end{aligned}$$

The functoriality of direct limits implies (2.1.18.1), while (2.1.18.2) comes from the universal property of direct limits. Then we have $\psi(\varepsilon) = \mu$, and hence $\psi \circ \varphi = \text{id}_{\text{Hom}_X(f^{-1}\mathcal{G}, \mathcal{F})}$. Similarly, we can also prove that $\varphi \circ \psi = \text{id}_{\text{Hom}_Y(\mathcal{G}, f_*\mathcal{F})}$ applying the universal properties of sheafification and direct limits. \square

Exercise 2.1.19 (Extending a Sheaf by Zero). *Let X be a topological space, let Z be a closed subset, let $i : Z \hookrightarrow X$ be the inclusion, let $U = X - Z$ be the complementary open subset and let $j : U \hookrightarrow X$ be its inclusion.*

(a) *Let \mathcal{F} be a sheaf on Z . Show that the stalk $(i_*\mathcal{F})_P$ of the direct image sheaf on X is \mathcal{F}_P if $P \in Z$, 0 if $P \notin Z$. Hence we call $i_*\mathcal{F}$ the sheaf obtained by extending \mathcal{F} by zero outside Z .*

(b) *Now let \mathcal{F} be a sheaf on U . Let $j_!\mathcal{F}$ be the sheaf on X associated to the presheaf $V \mapsto \mathcal{F}(V)$ if $V \subseteq U$, $V \mapsto 0$ otherwise. Show that the stalk $(j_!\mathcal{F})_P$ is equal to \mathcal{F}_P if $P \in U$, 0 if $P \notin U$, and show that $j_!\mathcal{F}$ is the only sheaf on X which has this property, and whose restriction to U is \mathcal{F} . We call $j_!\mathcal{F}$ the sheaf obtained by extending \mathcal{F} by zero outside U .*

(c) Now let \mathcal{F} be a sheaf on X . Show that there is an exact sequence of sheaves on X : $0 \rightarrow j_!(\mathcal{F}|_U) \rightarrow \mathcal{F} \rightarrow i_*(\mathcal{F}|_Z) \rightarrow 0$.

Proof. (a) For any open subset $V \subseteq X$, $(i_*\mathcal{F})(V) = \mathcal{F}(i^{-1}(V)) = \mathcal{F}(V \cap Z)$. Take $P \in V \cap Z$,

$$(i_*\mathcal{F})_P = \varinjlim_{P \in V \subseteq X} (i_*\mathcal{F})(V) = \varinjlim_{P \in V \subseteq X} \mathcal{F}(V \cap Z) = \varinjlim_{P \in W \subseteq Z} \mathcal{F}(W) = \mathcal{F}_P.$$

If $P \notin Z$, then there is an open subset $P \in V \subseteq U$ i.e. $V \cap Z = \emptyset$. Then $(i_*\mathcal{F})(V) = \mathcal{F}(\emptyset) = 0$, hence $(i_*\mathcal{F})_P = 0$.

(b) Assume \mathcal{G} is the presheaf $V \mapsto \mathcal{F}(V)$ if $V \subseteq U$ and $V \mapsto 0$ otherwise. For any $P \in U$, $(j_!(\mathcal{F})_P) = \mathcal{G}_P = \mathcal{F}_P$. If $P \notin U$, $(j_!(\mathcal{F}))_P = \mathcal{G}_P = 0$.

Suppose \mathcal{G}' is another sheaf satisfying the condition, then we get a natural morphism $\mathcal{G} \rightarrow \mathcal{G}'$, which induces $\varphi : j_!(\mathcal{F}) \rightarrow \mathcal{G}'$. If $P \in U$, we have $\varphi_P : \mathcal{F}_P \rightarrow \mathcal{G}'_P = \mathcal{F}_P$. If $P \notin U$, we have $\varphi_P : 0 \rightarrow 0$. Hence φ is an isomorphism.

(c) If $P \in U$, then $(j_!(\mathcal{F}|_U))_P = (\mathcal{F}|_U)_P = \mathcal{F}_P$ and $(i_*(\mathcal{F}|_Z))_P = 0$. This sequence is exact. If $P \in Z$, then $(j_!(\mathcal{F}|_U))_P = 0$ and $(i_*(\mathcal{F}|_Z))_P = ((\mathcal{F}|_Z))_P = \mathcal{F}_P$. This sequence is still exact. \square

2020.7.20 lc

Exercise 2.1.20 (Subsheaf with Supports). Let Z be a closed subset of X , and let \mathcal{F} be a sheaf on X . We define $\Gamma_Z(X, \mathcal{F})$ to be the subgroup of $\Gamma(X, \mathcal{F})$ consisting all sections whose support (Ex. 2.1.14) is contained in Z .

(a) Show that the presheaf $V \mapsto \Gamma_{V \cap Z}(V, \mathcal{F}|_V)$ is a sheaf. It is called the subsheaf of \mathcal{F} with supports in Z , and is denoted by $\mathcal{H}_Z^0(\mathcal{F})$.

(b) Let $U = X - Z$, and let $j : U \rightarrow X$ be the inclusion. Show there is an exact sequence of sheaves on X

$$0 \longrightarrow \mathcal{H}_Z^0(\mathcal{F}) \longrightarrow \mathcal{F} \xrightarrow{\varphi} j_*(\mathcal{F}|_U).$$

Furthermore, if \mathcal{F} is flasque, the map $\varphi : \mathcal{F} \rightarrow j_*(\mathcal{F}|_U)$ is surjective.

Proof. (a) Let $\{V_i\}_{i \in I}$ be an open cover of X and $t_i \in \Gamma_{V_i \cap Z}(V_i, \mathcal{F}|_{V_i}) \subseteq \mathcal{F}(V_i)$ with $t_i|_{V_i \cap V_j} = t_j|_{V_i \cap V_j}$ for any $i, j \in I$. Then there exists a unique section $t \in \Gamma(X, \mathcal{F})$ such that $t|_{V_i} = t_i$ for all $i \in I$ because \mathcal{F} is a sheaf. The uniqueness of such $t \in \Gamma(X, \mathcal{F})$ implies that there is at most one section $t \in \Gamma_Z(X, \mathcal{F})$ with $t|_{V_i} = t_i$ for all $i \in I$. To show the existence of such $t \in \Gamma_Z(X, \mathcal{F})$, we only need to show that the global section t constructed above lies in $\Gamma_Z(X, \mathcal{F})$. For any $x \in \text{Supp } t$, $x \in V_i$ for some $i \in I$. Thus $(t_i)_x = t_x \neq 0$, and hence $x \in \text{Supp } t_i \subseteq Z$. Then we have $\text{Supp } t \subseteq Z$ and therefore $t \in \Gamma_Z(X, \mathcal{F})$.

(b) Firstly, it is clear that for any open subset V , the morphism $\mathcal{H}_Z^0(\mathcal{F})(V) \rightarrow \mathcal{F}(V)$ is a natural inclusion and hence injective.

Then it suffices to show that $\ker \varphi = \mathcal{H}_Z^0(\mathcal{F})$.

Let $V \subseteq X$ be an open subset. If $V \cap U = \emptyset$, i.e. $V \subseteq Z$, then $\varphi(V) = 0$ and

$$\mathcal{H}_Z^0(\mathcal{F})(V) = \Gamma_{V \cap Z}(V, \mathcal{F}|_V) = \Gamma(V, \mathcal{F}|_V) = \mathcal{F}(V),$$

and hence $\ker \varphi(V) = \mathcal{H}_Z^0(\mathcal{F})(V)$.

If $V \cap U \neq \emptyset$, then $\varphi(V)(t) = t|_{V \cap U}$ for any $t \in \mathcal{F}(V)$. Thus for any $t \in \ker \varphi(V)$, $t_x = 0$ for each $x \in V \cap U$ and hence $\text{Supp } t \subseteq V - U = V \cap Z$, which implies that

$$t \in \Gamma_{V \cap Z}(V, \mathcal{F}|_V) = \mathcal{H}_Z^0(\mathcal{F})(V).$$

Then we have $\ker \varphi(V) \subseteq \mathcal{H}_Z^0(\mathcal{F})(V)$. On the other hand, if $t \in \mathcal{H}_Z^0(\mathcal{F})(V)$, $t_x = 0$ for any $x \in V \cap U$. Then we can get an open cover $\{V_i\}_{i \in I}$ of $V \cap U$ with $t|_{V_i} = 0$ for each $i \in I$. By

(a), $\mathcal{H}_Z^0(\mathcal{F})$ is a sheaf and so is $\mathcal{H}_Z^0(\mathcal{F})|_{V \cap U}$, so $\varphi(V)(t) = t|_{V \cap U} = 0$ and $t \in \ker \varphi(V)$. Then we have $\mathcal{H}_Z^0(\mathcal{F})(V) \subseteq \ker \varphi(V)$. Hence $\ker \varphi(V) = \mathcal{H}_Z^0(\mathcal{F})(V)$. Since V is an arbitrary open subset, $\ker \varphi = \mathcal{H}_Z^0(\mathcal{F})$. \square

Exercise 2.1.21 (Some Examples of Sheaves on Varieties). *Let X be a variety over an algebraically closed field k , as in Ch. 1. Let \mathcal{O}_X be the sheaf of regular functions on X .*

(a) *Let Y be a closed subset of X . For each open set $U \subseteq X$, let $\mathcal{I}_Y(U)$ be the ideal in the ring $\mathcal{O}_X(U)$ consisting of those regular functions which vanish at all points of $Y \cap U$. Show that the presheaf $U \mapsto \mathcal{I}_Y(U)$ is a sheaf. It is called the sheaf of ideals \mathcal{I}_Y of Y , and it is a subsheaf of the sheaf of rings \mathcal{O}_X .*

(b) *If Y is a subvariety, then the quotient sheaf $\mathcal{O}_X/\mathcal{I}_Y$ is isomorphic to $i_*\mathcal{O}_Y$, where $i: Y \rightarrow X$ is the inclusion and \mathcal{O}_Y is the sheaf of regular functions on Y .*

(c) *Now let $X = \mathbb{P}^1$, and let Y be the union of two distinct points $P, Q \in X$. Then there is an exact sequence of sheaves on X , where $\mathcal{F} = i_*\mathcal{O}_P \oplus i_*\mathcal{O}_Q$,*

$$0 \longrightarrow \mathcal{I}_Y \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{F} \longrightarrow 0.$$

Show however that the induced map on $\Gamma(X, \mathcal{O}_X) \rightarrow \Gamma(X, \mathcal{F})$ is not surjective. This shows that the global section functor $\Gamma(X, -)$ is not exact (cf. (Ex. 2.1.8) which shows that it is left exact).

(d) *Again let $X = \mathbb{P}^1$ and let \mathcal{O} be the sheaf of regular functions. Let \mathcal{H} be the constant sheaf on X associated to the function field K of X . Show that there is a natural injection $\mathcal{O} \rightarrow \mathcal{H}$. Show that the quotient \mathcal{H}/\mathcal{O} is isomorphic to the direct sum of sheaves $\sum_{P \in X} i_P(I_P)$, where I_P is the group K/\mathcal{O}_P , and $i_P(I_P)$ denotes the skyscraper sheaf (Ex. 2.1.17) given by I_P at the point P .*

(e) *Finally show that in the case of (d) the sequence*

$$0 \longrightarrow \Gamma(X, \mathcal{O}) \longrightarrow \Gamma(X, \mathcal{H}) \xrightarrow{\psi} \Gamma(X, \mathcal{H}/\mathcal{O}) \longrightarrow 0$$

is exact. (This is an analogue of what is called the “first Cousin problem” in several complex variables.)

Proof. (a) Let $\{U_i\}_{i \in I}$ be an open cover of X . Assume that $\{s_i\}_{i \in I}$ satisfies that $s_i \in \mathcal{I}_Y(U_i) \subseteq \mathcal{O}_X(U_i)$ and $s_i|_{U_i \cap U_j} = s_j|_{U_i \cap U_j}$ for any $i, j \in I$. Then there exists a unique section $s \in \Gamma(X, \mathcal{O}_X)$ with $s|_{U_i} = s_i$ for all $i \in I$ because \mathcal{O}_X is a sheaf. The uniqueness of such $s \in \Gamma(X, \mathcal{O}_X)$ implies that there is at most one global section $s \in \Gamma(X, \mathcal{I}_Y)$ with $s|_{U_i} = s_i$ for all $i \in I$. To show the existence of such $s \in \Gamma(X, \mathcal{I}_Y)$, we only need to show that the global section s constructed above lies in $\Gamma(X, \mathcal{I}_Y)$. For any $x \in Y$, $x \in U_i$ for some $i \in I$. Then $s(x) = s_i(x) = 0$. Thus s vanishes at all points of Y . And hence $s \in \Gamma(X, \mathcal{I}_Y)$.

(b) By Proposition 2.1.1, it suffices to show that $(\mathcal{O}_X/\mathcal{I}_Y)_x \simeq (i_*\mathcal{O}_Y)_x$ for all $x \in X$. We may assume that X and Y are affine varieties without loss of generality. If $x \notin Y$, $(i_*\mathcal{O}_Y)_x = 0$ and

$$\mathcal{I}_{Y,x} = \varinjlim_{x \in U \subseteq X-Y} \mathcal{I}_Y(U) = \varinjlim_{x \in U \subseteq X-Y} \mathcal{O}_X(U) = \mathcal{O}_{X,x}.$$

Thus $(\mathcal{O}_X/\mathcal{I}_Y)_x = 0 = (i_*\mathcal{O}_Y)_x$. Assume $x \in Y$. Write $A = \Gamma(X, \mathcal{O}_X)$ and $I = \Gamma(X, \mathcal{I}_Y)$. Then $A/I \simeq \Gamma(Y, \mathcal{O}_Y)$. Let M_x, \mathfrak{m}_x be the maximal ideal of $A, A/I$ respectively corresponding to x . Then

$$(\mathcal{O}_X/\mathcal{I}_Y)_x \simeq A_{M_x}/IA_{M_x} \simeq (A/I)_{\mathfrak{m}_x} \simeq (i_*\mathcal{O}_Y)_x,$$

which follows the flatness of localization.

(c) By Ex. 2.1.2, it suffices to show that the sequences

$$0 \longrightarrow \mathcal{I}_{Y,x} \longrightarrow \mathcal{O}_{X,x} \xrightarrow{\varphi_x} \mathcal{F}_x \longrightarrow 0$$

are exact for all $x \in X$. The first morphism is a natural inclusion and hence injective. If $x \notin Y$, $\mathcal{F}_x = 0$, $\mathcal{I}_{Y,x} = \mathcal{O}_{X,x}$ and $\varphi_x = 0$. If $x \in Y$, assume $x = P$ without loss of generality. Thus $\mathcal{I}_{Y,P}$ is the unique maximal ideal of $\mathcal{O}_{X,P}$, $\mathcal{F}_P = (i_*\mathcal{O}_P)_P \oplus (i_*\mathcal{O}_Q)_P = \mathcal{O}_{P,P} = k$ and $\varphi_P(t) = t(P)$ for $t \in \mathcal{O}_{X,P}$. Then we may conclude that φ_x is surjective and $\ker \varphi_x = \mathcal{I}_{Y,x}$.

However, $\Gamma(X, \mathcal{O}_X) = k$ and

$$\Gamma(X, \mathcal{F}) = \Gamma(X, i_*\mathcal{O}_P) \oplus \Gamma(X, i_*\mathcal{O}_Q) = k \oplus k,$$

so $\Gamma(X, \mathcal{O}_X) \rightarrow \Gamma(X, \mathcal{F})$ is not surjective.

(d) For any open subset $U \subseteq X$, define the natural map $\mathcal{O}(U) \rightarrow \mathcal{H}(U) = K$ by sending $f \in \mathcal{O}(U)$ to the equivalent class represented by (U, f) . If $(U, f) = 0$, there exists a nonempty open subset $V \subseteq U$ such that $f|_V = 0$. Then by Lemma 1.4.1, $f = 0$. Hence the natural map defined above is injective.

To show that $\mathcal{H}/\mathcal{O} \simeq \sum_{P \in X} i_P(I_P)$, we only need to show that

$$(\mathcal{H}/\mathcal{O})_x \simeq \left(\sum_{P \in X} i_P(I_P) \right)_x$$

for any $x \in X$. It is clear that $(\mathcal{H}/\mathcal{O})_x \simeq \mathcal{H}_x/\mathcal{O}_x = K/\mathcal{O}_x$. By Ex. 2.1.17,

$$\left(\sum_{P \in X} i_P(I_P) \right)_x \simeq \sum_{P \in X} (i_P(I_P))_x = \sum_{x \in \{P\}^-} I_P = I_x = K/\mathcal{O}_x,$$

since $\{P\}$ is closed in X for any $P \in X$.

(e) It is clear that $\Gamma(X, \mathcal{O}) = k$, $\Gamma(X, \mathcal{H}) = K$ and the first morphism is the natural inclusion and hence injective. And the isomorphism in (d) implies that

$$\Gamma(X, \mathcal{H}/\mathcal{O}) \simeq \Gamma \left(X, \sum_{P \in X} i_P(I_P) \right) = \sum_{P \in X} I_P = \sum_{P \in X} K/\mathcal{O}_P.$$

By Lemma 1.6.4 and Lemma 1.6.5, for any $f \in K$, there are only finitely many $P \in X$ such that $x \notin \mathcal{O}_P$. Hence the natural morphism

$$\psi : \Gamma(X, \mathcal{H}) = K \longrightarrow \sum_{P \in X} K/\mathcal{O}_P \simeq \Gamma(X, \mathcal{H}/\mathcal{O})$$

is well-defined.

Assume $s = (s_1, \dots, s_r, 0, \dots) \in \sum_{P \in X} K/\mathcal{O}_P$, where $P_i \in X$ and $s_i \in K/\mathcal{O}_{P_i}$ nonzero for $i = 1, \dots, r$. Assume $P_1, \dots, P_r \in \{(x_0 : x_1) \in \mathbb{P}^1 \mid x_1 \neq 0\}$. Then we have $K \simeq k(T)$ and $\mathcal{O}_{P_i} \simeq k[T]_{(T-p_i)}$ for some $p_i \in K$, for $i = 1, \dots, r$. Thus we may write

$$s_i = \frac{f_i(T)}{(T-p_i)^{d_i}} \mod \mathcal{O}_{P_i},$$

where $f_i \in k[T]$, for $i = 1, \dots, r$, because any $\frac{g(T)}{h(T)} \in K$ can be written as $\frac{g_1(T)}{(T-a_1)^{n_1}} + \dots + \frac{g_l(T)}{(T-a_l)^{n_l}}$, where $h, g, g_1, \dots, g_l \in k[T]$ and $h(T) = (T-a_1)^{n_1} \dots (T-a_l)^{n_l}$. Let

$$f(T) = \frac{f_1(T)}{(T-p_1)^{d_1}} + \dots + \frac{f_r(T)}{(T-p_r)^{d_r}} \in K.$$

Then $\psi(f) = s$. Hence $\psi : \Gamma(X, \mathcal{H}) \rightarrow \Gamma(X, \mathcal{H}/\mathcal{O})$ is surjective.

Since $k = \bigcap_{P \in X} \mathcal{O}_P$, $k = \ker \psi$. Above all, the sequence

$$0 \longrightarrow \Gamma(X, \mathcal{O}) \longrightarrow \Gamma(X, \mathcal{H}) \xrightarrow{\psi} \Gamma(X, \mathcal{H}/\mathcal{O}) \longrightarrow 0$$

is exact. □

2021.7.21 ysh

Exercise 2.1.22 (Gluing Sheaves). *Let X be a topological space, let $\mathfrak{U} = \{U_i\}$ be an open cover of X , and suppose we are given for each i a sheaf \mathcal{F}_i on U_i , and for each i, j an isomorphism $\varphi_{ij} : \mathcal{F}_i|_{U_i \cap U_j} \rightarrow \mathcal{F}_j|_{U_i \cap U_j}$ such that (1) for each i , $\varphi_{ii} = \text{id}$, and (2) for each i, j, k , $\varphi_{ik} = \varphi_{jk} \circ \varphi_{ij}$ on $U_i \cap U_j \cap U_k$. Then there exists a unique sheaf \mathcal{F} on X , together with isomorphisms $\psi_i : \mathcal{F}|_{U_i} \rightarrow \mathcal{F}_i$ such that for each i, j , $\psi_j = \varphi_{ij} \circ \psi_i$ on $U_i \cap U_j$. We say loosely that \mathcal{F} is obtained by gluing the sheaves \mathcal{F}_i via the isomorphisms φ_{ij} .*

Proof. Define

$$\mathcal{F}(V) = \left\{ (s_i) \in \prod_i \mathcal{F}_i(V \cap U_i) \mid \varphi_{ij}(V \cap U_i \cap U_j)(s_i|_{V \cap U_i \cap U_j}) = s_j|_{V \cap U_i \cap U_j} \right\}.$$

This is well-defined because of the compatibility of the φ on each triple intersection. For $W \subseteq V$, there is a map $\mathcal{F}(V) \rightarrow \mathcal{F}(W)$ induced by each $\mathcal{F}_i(V \cap U_i) \rightarrow \mathcal{F}_i(W \cap U_i)$. We let these be the restriction maps of \mathcal{F} , so it is clear that \mathcal{F} is a presheaf. Now let $\{V_j\}$ be a covering of V , and suppose that $s \in \mathcal{F}(V)$ is such that $s|_{V_j} = 0$ for all j . More precisely, for each component $s_i \in \mathcal{F}_i(V \cap U_i)$ of s , $s_i|_{V_j} = 0$ for all j . For any given i , $\{U_i \cap V_j\}$ is a covering of $U_i \cap V$, and \mathcal{F}_i is a sheaf, so this implies $s_i = 0$ for all i , and hence $s = 0$. Now suppose there are $s^j \in \mathcal{F}(V_j)$ such that for all j and k , $s^j|_{V_j \cap V_k} = s^k|_{V_j \cap V_k}$. For fixed i , $\{U_i \cap V_j\}$ is a covering of $U_i \cap V$, and $s_i^j|_{V_j \cap V_k} = s_i^k|_{V_j \cap V_k}$. Since \mathcal{F}_i is a sheaf, there is an element s_i such that $s_i|_{V_j} = s_i^j$ for all j . Furthermore, these elements satisfy the condition $\varphi_{ij}(s_i|_{V \cap U_i \cap U_j}) = s_j|_{V \cap U_i \cap U_j}$, so they are the components of some $s \in \mathcal{F}(V)$, and therefore \mathcal{F} is a sheaf. For every inclusion of open sets $V \subseteq U_i$, $(\mathcal{F}|_{U_i})(V) = \mathcal{F}(V)$, so there is a morphism $\psi_i(V) : (\mathcal{F}|_{U_i})(V) \rightarrow \mathcal{F}_i(V)$ by $s \mapsto s_i$. To see this is injective, suppose there is t such that the component of t in $\mathcal{F}_i(V)$ is s_i . Then for any j , $\varphi_{ji}(t_j|_{V \cap U_j}) = t_i|_{V \cap U_j} = s_i|_{V \cap U_j}$. Since φ_{ji} is an isomorphism, $t_j|_{V \cap U_j} = s_j|_{V \cap U_j}$, so $t = s$. For surjectivity, we can define $s_j = \varphi_{ij}(s_i|_{V \cap U_i})$, which is an element of $V \cap U_j$, and by definition this gives an element of $\mathcal{F}(V)$. The map $s \mapsto s_i$ gives rise to an isomorphism $\psi_i : \mathcal{F}|_{U_i} \rightarrow \mathcal{F}_i$. That $\psi_j = \varphi_{ij} \circ \psi_i$ on $U_i \cap U_j$ for all i and j is a consequence of the definition of the elements in $\mathcal{F}(X)$. □

2.2. Schemes.

Exercise 2.2.1. *Let A be a ring, let $X = \text{Spec } A$, let $f \in A$ and let $D(f) \subseteq X$ be the open complement of $V((f))$. Show that the locally ringed space $(D(f), \mathcal{O}_X|_{D(f)})$ is isomorphic to $\text{Spec } A_f$.*

Proof. Let Y denote the affine scheme $\text{Spec } A_f$. Then we canonically have a topological open immersion $i : Y \rightarrow X$ whose image is $D(f)$. Let $D(h)$ be a principal open subset of X contained in $D(f)$. Let \bar{h} be the image of h in A_f . We canonically have

$$\mathcal{O}_X(D(h)) = A_h \simeq (A_f)_{\bar{h}} = \mathcal{O}_Y(D(\bar{h})) = i_*\mathcal{O}_Y(D(h)).$$

As the $D(h)$ form a base of open subsets on $D(f)$, this shows that i induces an isomorphism from (Y, \mathcal{O}_Y) onto $(D(f), \mathcal{O}_X|_{D(f)})$. □

2021.7.22 Chow Y-N

Exercise 2.2.2. Let (X, \mathcal{O}_X) be a scheme, and let $U \subseteq X$ be any open subset. Show that $(U, \mathcal{O}_X|_U)$ is a scheme. We call this the induced scheme structure on the open set U , and we refer to $(U, \mathcal{O}_X|_U)$ as an open subscheme of X .

Proof. Let $\text{Spec } A_i$ be an affine open cover for X . The intersection of each $\text{Spec } A_i$ with U is an open subset of $\text{Spec } A_i$ which is therefore covered by basic open affines $D(f_{ij})$. Hence, we obtain an open affine cover $\text{Spec } (A_i)_{f_{ij}}$ for U . \square

Exercise 2.2.3 (Reduced Schemes). A scheme (X, \mathcal{O}_X) is reduced if for every open set $U \subseteq X$, the ring $\mathcal{O}_X|_U$ has no nilpotent elements.

(a) Show that (X, \mathcal{O}_X) is reduced if and only if for every $P \in X$, the local ring $\mathcal{O}_{X,P}$ has no nilpotent elements.

(b) Let (X, \mathcal{O}_X) be a scheme. Let $(\mathcal{O}_X)_{\text{red}}$ be the sheaf associated to the presheaf $U \mapsto \mathcal{O}_X(U)_{\text{red}}$, where for any ring A , we denote by A_{red} the quotient of A by its ideal of nilpotent elements. Show that $(X, (\mathcal{O}_X)_{\text{red}})$ is a scheme. We call it the reduced scheme associated to X , and denote it by X_{red} . Show that there is a morphism of schemes $X_{\text{red}} \rightarrow X$, which is a homeomorphism on the underlying topological spaces.

(c) Let $f : X \rightarrow Y$ be a morphism of schemes, and assume that X is reduced. Show that there is a unique morphism $g : X \rightarrow Y_{\text{red}}$ such that f is obtained by composing g with the natural map $Y_{\text{red}} \rightarrow Y$.

Proof. (a) Nilpotent is a local-global property. Let $S(A) = \{\text{minimal prime ideals of } A\}$ and $\mathfrak{N}(A) = \{\text{nilpotent elements of } A\}$. Consider an affine open set $\text{Spec } A$, a result of commutative algebra is $\mathfrak{N}(A) = \bigcap_{\mathfrak{p} \in S(A)} \mathfrak{p}$. Thus

$$\begin{aligned} \mathfrak{N}(A) = 0 &\iff \bigcap_{\mathfrak{p} \in S(A)} \mathfrak{p} = 0 \\ &\iff \text{for any } \mathfrak{p}, \bigcap_{\mathfrak{p}_i \subseteq \mathfrak{p}} \mathfrak{p}_i = 0 \\ &\iff \mathfrak{N}(A_{\mathfrak{p}}) = 0. \end{aligned}$$

(b) For a basic open affine $D(f)$ we have

$$\mathcal{O}_{\text{Spec}(A_{\text{red}})}(D(f)) \simeq (A/\mathfrak{N})_f \simeq A_f / (\mathfrak{N}(A_f)).$$

That is, on a basic open affine U we have $\mathcal{O}_{\text{Spec}(A_{\text{red}})}|_U \simeq \mathcal{O}_{(\text{Spec } A)_{\text{red}}}|_U$. Since the basic opens cover X this shows that $\text{Spec } A_{\text{red}} \simeq (X, (\mathcal{O}_X)_{\text{red}})$. Now for a general scheme X , a cover of X with open affines $\text{Spec } A_i$ gives a cover $\text{Spec } (A_i)_{\text{red}}$ for $(X, (\mathcal{O}_X)_{\text{red}})$. Hence, the latter is a scheme.

It suffices to check the homeomorphism locally, this follows from the fact that \mathfrak{N} is the intersection of all minimal prime ideals, so that we lose nothing topologically.

(c) We need to prove that any morphism from a reduced scheme to Y factors through Y_{red} . We just need to consider the local affine case, and to patch them all together. Let $V_i = \text{Spec } B_i$ be an open affine cover for Y , and let $U_{ij} = \text{Spec } A_{ij}$ be an open affine cover of $f^{-1}(V_i)$. As in the previous part $V_i^{\text{red}} = \text{Spec } B_i^{\text{red}}$ is an open affine cover for Y_{red} and the morphism $Y_{\text{red}} \rightarrow Y$ is induced by the ring homomorphisms $B_i \rightarrow B_i^{\text{red}}$. Now since each A_{ij} is reduced, $\mathfrak{N}(B_i)$ is in the kernel of each of the ring homomorphisms $B_i \rightarrow A_{ij}$ and so these factor uniquely as $B_i \rightarrow B_i^{\text{red}} \rightarrow A_{ij}$. So the morphisms $U_{ij} \rightarrow V_i$ factor uniquely as $U_{ij} \rightarrow V_i^{\text{red}} \rightarrow V_i$. The same is true of each intersection of U_{ij} 's and so this gives rise to a unique factorization $f^{-1}(V_i) \rightarrow V_i^{\text{red}} \rightarrow V_i$. \square

Exercise 2.2.4. Let A be a ring and let (X, \mathcal{O}_X) be a scheme. Given a morphism $f : X \rightarrow \operatorname{Spec} A$, we have an associated map on sheaves $f^\# : \mathcal{O}_{\operatorname{Spec} A} \rightarrow f_* \mathcal{O}_X$. Taking global sections we obtain a homomorphism $A \rightarrow \Gamma(X, \mathcal{O}_X)$. Thus there is a natural map

$$\alpha : \operatorname{Hom}_{\mathfrak{Sch}}(X, \operatorname{Spec} A) \longrightarrow \operatorname{Hom}_{\mathfrak{Ring}}(A, \Gamma(X, \mathcal{O}_X)) .$$

Show that α is bijective (cf. (Proposition 1.3.5) for an analogous statement about varieties).

Proof[†]. The proposition says that $\operatorname{Spec}(-) : \mathfrak{Ring} \rightarrow \mathfrak{Sch}$ is a right adjoint to $\Gamma(-, \mathcal{O}_-) : \mathfrak{Sch} \rightarrow \mathfrak{Ring}$. Let F be Γ , G be Spec . That's we need to show there exists two natural transformation:

$$\eta : \operatorname{id}_{\mathfrak{Sch}} \longrightarrow \operatorname{Spec} \circ \Gamma \quad \text{and} \quad \varepsilon : \Gamma \circ \operatorname{Spec} \longrightarrow \operatorname{id}_{\mathfrak{Ring}}$$

such that $F \xrightarrow{F\eta} FGF \xrightarrow{\varepsilon F} F$ and $G \xrightarrow{\eta G} GFG \xrightarrow{G\varepsilon} G$ equal the identity on F and G respectively. It's straightforward to prove $F \xrightarrow{F\eta} FGF \xrightarrow{\varepsilon F} F$ and the other. The obvious choice for ε is the isomorphism of Proposition 2.2.2 (c). For a scheme X we define the natural transformation η as follows. Let $U_i = \operatorname{Spec} A_i$ be an affine cover of the scheme. Each restriction $\Gamma X \rightarrow A_i$ gives a morphism $\operatorname{Spec} A_i \rightarrow \operatorname{Spec} \Gamma X$ and since the restriction $\Gamma X \rightarrow \mathcal{O}_X(U_i) \rightarrow \mathcal{O}_X(U_{ij})$ is the same as $\Gamma X \rightarrow \mathcal{O}_X(U_j) \rightarrow \mathcal{O}_X(U_{ij})$ these morphisms glue to give a morphism $X \rightarrow \operatorname{Spec} \Gamma X$. Given any scheme X , we define a morphism $X \rightarrow \operatorname{Spec} \Gamma X$ as follows: for any open affine set U , the open immersion $U \hookrightarrow X$ induces a restriction $\mathcal{O}_X(X) \rightarrow \mathcal{O}_X(U)$, and take the Spec we get the map from U to $\operatorname{Spec}(\mathcal{O}_X(X))$, and we patch the local morphisms all together. \square

2021.7.26 wxj

Exercise 2.2.5. Describe $\operatorname{Spec} \mathbb{Z}$, and show that it is a final object for the category of schemes.

Proof. $\operatorname{Spec} \mathbb{Z} = \{0\} \cup \{(p) \mid p \text{ is prime in } \mathbb{Z}\}$. The closed sets are all finite sets consist of ideals generated by prime numbers. It is also easy to show that all open subsets of $\operatorname{Spec} \mathbb{Z}$ are principle, which is also true for the spectrum of the integral closure of \mathbb{Z} in any number field (see [Liu02, Ch. 2, Ex. 3.19, P. 58]).

Since $\alpha : \operatorname{Hom}_{\mathfrak{Sch}}(X, \operatorname{Spec} \mathbb{Z}) \rightarrow \operatorname{Hom}_{\mathfrak{Ring}}(\mathbb{Z}, \Gamma(X, \mathcal{O}_X))$ is a bijection by Ex. 2.2.4. With the fact that there is a unique homomorphism $\mathbb{Z} \rightarrow A$, by sending n to $n \cdot 1_A$ for any unitary commutative ring A , we can conclude that there exists a unique morphism $X \rightarrow \operatorname{Spec} \mathbb{Z}$. \square

Exercise 2.2.6. Describe the spectrum of the zero ring, and show that it is an initial object for the category of schemes.

Proof. $\operatorname{Spec} 0 = \emptyset$. For any scheme X , $\emptyset \rightarrow X$ is clearly a trivial map, then $\operatorname{Spec} 0$ is an initial object in the category of schemes. \square

2021.7.27 lc

Exercise 2.2.7. Let X be a scheme. For any $x \in X$, let \mathcal{O}_x be the local ring at x , and \mathfrak{m}_x its maximal ideal. We define the residue field of x on X to be the field $k(x) = \mathcal{O}_x / \mathfrak{m}_x$. Now let K be any field. Show that to give a morphism of $\operatorname{Spec} K$ to X it is equivalent to give a point x and an inclusion map $k(x) \rightarrow K$.

Proof. We want to show that there are bijections

$$\operatorname{Hom}_{\mathfrak{Sch}}(\operatorname{Spec} K, X) \xrightleftharpoons[\beta]{\alpha} \{(x, k(x) \hookrightarrow K) \mid x \in X, \operatorname{Hom}(k(x), K) \neq \emptyset\} .$$

Firstly, we can see that

$$\mathrm{Spec} K = \{\eta\} \quad \text{and} \quad \mathcal{O}_{\mathrm{Spec} K, \eta} = K.$$

(1) Let $(f, f^\#) : \mathrm{Spec} K \rightarrow X$ and $x = f(\eta)$. Then we have a local homomorphism $f_x^\# : \mathcal{O}_x \rightarrow K$ which induces an inclusion $\bar{f} : k(x) \rightarrow K$. Thus define $\alpha(f, f^\#) = (x, \bar{f})$.

(2) Given $x \in X$ and an inclusion $i : k(x) \rightarrow K$, we can define $f : \mathrm{Spec} K \rightarrow X$ by sending η to x and

$$p : \mathcal{O}_x \longrightarrow k(x) \xrightarrow{i} K, \quad a \longmapsto a + \mathfrak{m} \longmapsto i(a + \mathfrak{m}_x) .$$

With the fact that

$$f_* \mathcal{O}_{\mathrm{Spec} K}(U) = \begin{cases} K, & \text{if } x \in U \\ 0, & \text{otherwise,} \end{cases}$$

we can define $\beta(x, i) = f^\# : \mathcal{O}_x \rightarrow f_* \mathcal{O}_{\mathrm{Spec} K}$ as: if $x \notin U$, $f^\#(U)$ is zero map; if $x \in U$,

$$f^\#(U) : \mathcal{O}_X(U) \longrightarrow \mathcal{O}_x \xrightarrow{p} f_* \mathcal{O}_{\mathrm{Spec} K}(U) .$$

It is easy to verify that α and β are invertible to each other with the fact that $f_x^\# = p$ where $f^\#$ and p are defined in (2). \square

Exercise 2.2.8. Let X be a scheme. For any $x \in X$, we define the Zariski tangent space T_x to X at x to be the dual of the $k(x)$ -vector space $\mathfrak{m}_x/\mathfrak{m}_x^2$. Now assume that X is a scheme over a field k , and let $k[\varepsilon]/(\varepsilon^2)$ be the ring of dual numbers over k . Show that to give a k -morphism of $\mathrm{Spec} k[\varepsilon]/(\varepsilon^2)$ to X it is equivalent to give a point $x \in X$, rational over k (i.e., such that $k(x) = k$), and an element of T_x .

Proof. We want to show that there are bijections

$$\mathrm{Hom}_k(\mathrm{Spec} k[\varepsilon]/(\varepsilon^2), X) \xrightleftharpoons[\beta]{\alpha} \{(x, t) \mid x \in X, \text{ rational over } k, \text{ and } t \in T_x\} .$$

Use simple notations S and $k[\varepsilon]$ instead of $\mathrm{Spec} k[\varepsilon]/(\varepsilon^2)$ and $k[\varepsilon]/(\varepsilon^2)$ respectively. With easy calculation, we have

$$S = \{(\varepsilon)\} \quad \text{and} \quad \mathcal{O}_{S, (\varepsilon)} = k[\varepsilon].$$

(1) Assume $(f, f^\#) \in \mathrm{Hom}_k(S, X)$. Let $x = f((\varepsilon))$. Then we get a local k -homomorphism

$$f_x^\# : \mathcal{O}_{X, x} \longrightarrow \mathcal{O}_{S, (\varepsilon)} = k[\varepsilon]$$

which induces an inclusion $k(x) \hookrightarrow k[\varepsilon]$. On the other hand, $k(x)$ is a finite extension over k . Thus we can conclude that $k(x) = k$; otherwise suppose that $a \in k(x) - k$, then we can write $a = a_1 + a_2\varepsilon$ for some $a_1, a_2 \in k$, and hence $\varepsilon \in k$ which is a contradiction.

The local k -homomorphism $f_x^\#$ maps the maximal ideal \mathfrak{m}_x to $(\varepsilon) = k\varepsilon$. Since $\varepsilon^2 = 0$, we have $\mathfrak{m}_x^2 \subseteq \ker f_x^\#$. Hence with the natural k -isomorphism $k\varepsilon \rightarrow k$ sending $a\varepsilon$ to a , we can obtain a k -homomorphism

$$t : \mathfrak{m}_x/\mathfrak{m}_x^2 \longrightarrow k\varepsilon \longrightarrow k .$$

Define $\alpha(f, f^\#) = (x, t)$.

(2) Given a k -rational point $x \in X$ and $t \in T_x$, we can define $f : S \rightarrow X$ by sending (ε) to x and

$$q : \mathfrak{m}_x \longrightarrow \mathfrak{m}_x/\mathfrak{m}_x^2 \xrightarrow{t} k \longrightarrow k\varepsilon .$$

With the following exact sequence, where p and i are natural projection and inclusion with $p \circ i = \text{id}_k$, we have $\mathcal{O}_{X,x} \cong k \oplus \mathfrak{m}_x$, applying the splitting lemma.

$$0 \longrightarrow \mathfrak{m}_x \longrightarrow \mathcal{O}_{X,x} \begin{array}{c} \xrightarrow{p} \\ \xleftarrow{i} \end{array} k \longrightarrow 0 .$$

Then we can define

$$q' : \mathcal{O}_{X,x} \simeq k \oplus \mathfrak{m}_x \longrightarrow k[\varepsilon] = \mathcal{O}_{S,(\varepsilon)}, \quad (a, r) \longrightarrow a + q(r) .$$

With the fact that

$$f_* \mathcal{O}_S(U) = \begin{cases} k[\varepsilon], & \text{if } x \in U \\ 0, & \text{otherwise,} \end{cases}$$

we can define $\beta(x, t) = f^\# : \mathcal{O}_X \rightarrow f_* \mathcal{O}_S$ as: if $x \notin U$, $f^\#(U)$ is zero map; if $x \in U$,

$$f^\#(U) : \mathcal{O}_X(U) \longrightarrow \mathcal{O}_{X,x} \xrightarrow{q} f_* \mathcal{O}_S(U) .$$

It is easy to verify that α and β are invertible to each other with the fact that $f_x^\# = q'$ where $f^\#$ and q' are defined in (2). \square

Exercise 2.2.9. If X is a topological space, and Z an irreducible closed subset of X , a generic point for Z is a point ζ such that $Z = \{\zeta\}^-$. If X is a scheme, show that every (nonempty) irreducible closed subset has a unique generic point.

Proof. Uniqueness: Suppose ζ_1, ζ_2 are two generic points of Z . Then since $\{\zeta_i\}^- = Z$, an open set contains ζ_1 iff it contains ζ_2 . Letting $U = \text{Spec } A$ be an affine neighbourhood of ζ_1 , we identify $\zeta_i|_U = \mathfrak{p}_i \in \text{Spec } R$. Since $\mathfrak{p}_2 \in \{\mathfrak{p}_1\}^-$, we have $\mathfrak{p}_2 \supseteq \mathfrak{p}_1$ and vice versa, so $\zeta_1 = \zeta_2$.

Existence: Let X be a scheme, $Z \subseteq X$ closed and irreducible. If $U \subseteq Z$ is open and $\zeta \in U$ such that $\{\zeta\}^- = U$, then $\{\zeta\}^- = Z$ in X since Z is irreducible. So we can assume that $X = \text{Spec } A$ is affine and $Z = V(\mathfrak{a}) \simeq \text{Spec } A/\mathfrak{a}$ for some ideal $\mathfrak{a} \subseteq A$. Now we can further assume that $Z = X = \text{Spec } A$ is irreducible. It follows that there can only be one minimal prime ideal whose closure is all of X . \square

Exercise 2.2.10. Describe $\text{Spec } \mathbb{R}[x]$. How does its topological space compare to the set \mathbb{R} ? To \mathbb{C} ?

Proof. The prime ideals of $\mathbb{R}[x]$ fall into three types: (1) The generic point (0), with residue field $\mathbb{R}(x)$. (2) Closed points of the form $(x - \alpha)$ with $\alpha \in \mathbb{R}$. The residue field in each case is \mathbb{R} . (3) Closed points of the form $(x^2 + \alpha x + \beta)$, with residue field \mathbb{C} . As a set, there is a bijection between $\text{Spec } \mathbb{R}[x]$ and the upper complex plane \mathbb{H} by sending $z \in \mathbb{H}$ to $(x - z)(x - \bar{z})$ if $z \notin \mathbb{R}$ and to $(x - z)$ if $z \in \mathbb{R}$.

There are quite a lot differences between the topological spaces $\text{Spec } \mathbb{R}[x]$ and \mathbb{R} (or \mathbb{C}). For instance, (1) \mathbb{R} is Hausdorff, but $\text{Spec } \mathbb{R}[x]$ is not; (2) $\text{Spec } \mathbb{R}[x]$ is quasi-compact, but \mathbb{R} is not; (3) $\text{Spec } \mathbb{R}[x]$ has a generic point, but \mathbb{R} does not; (4) The map $\mathbb{R} \rightarrow \text{Spec } \mathbb{R}[x]$ defined above is continuous, but $\text{Spec } \mathbb{R}[x] \rightarrow \mathbb{H} \hookrightarrow \mathbb{C}$ is not. \square

Exercise 2.2.11. Let $k = \mathbb{F}_p$ be the finite field with p elements. Describe $\text{Spec } k[x]$. What are the residue fields of its points? How many points are there with a given residue field?

Proof. The space: the generic point and one point for every monic irreducible polynomial.

The residue field of the generic point is the fractional field, and is \mathbb{F}_{p^n} if the point corresponds to a polynomial of degree n .

Thus to count the number of points with a given residue field \mathbb{F}_{p^n} , it suffices to count the number of monic irreducible polynomials with degree n . Moreover it's equivalent to count the number of elements of \mathbb{F}_{p^n} not contained in any subfield (i.e. the order is p^n), since every irreducible polynomial $f(x)$ of degree n gives n elements of \mathbb{F}_{p^n} via the isomorphism $\mathbb{F}_p[x]/(f(x)) \rightarrow \mathbb{F}_{p^n}$ and every element α of \mathbb{F}_{p^n} that is not contained in any subfields gives an irreducible polynomial of degree n by taking its minimal polynomial $\prod_{i=0}^{n-1} (x - \alpha^{p^i})$, and these processes are inverses of each other. Use the Möbius inverse formula we get the answer: $\frac{1}{n} \sum_{d|n} \mu(d) p^d$. \square

Exercise 2.2.12 (Glueing Lemma). *Let $\{X_i\}$ be a family of schemes (possibly infinite). For each $i \neq j$, suppose given an open subset $U_{ij} \subseteq X_i$ and let it have the induced scheme structure. Suppose also given for each $i \neq j$ an isomorphism of schemes $\varphi_{ij} : U_{ij} \rightarrow U_{ji}$ such that (1) for each $i, j, \varphi_{ji} = \varphi_{ij}^{-1}$, and (2) for each i, j, k , $\varphi_{ij}(U_{ij} \cap U_{ik}) = U_{ji} \cap U_{jk}$, and $\varphi_{ik} = \varphi_{jk} \circ \varphi_{ij}$ on $U_{ij} \cap U_{ik}$.*

Then show that there is a scheme X , together with morphisms $\psi_i : X_i \rightarrow X$ for each i , such that (1) ψ_i is an isomorphism of X_i onto an open subscheme of X , (2) the $\psi_i(X_i)$ cover X , (3) $\psi_i(U_{ij}) = \psi_i(X_i) \cap \psi_j(X_j)$ and (4) $\psi_i = \psi_j \circ \varphi_{ij}$ on U_{ij} . We say that X is obtained by glueing the schemes X_i along the isomorphisms φ_{ij} . An interesting special case is when the family X_i is arbitrary, but the U_{ij} and φ_{ij} are all empty. Then the scheme X is called the disjoint union of the X_i , and is denoted $\coprod X_i$.

Proof. We can view a scheme as a functor, and the exercise just says that it's a sheaf in the Zariski site. We give a brief construction without too much check:

Define a topological space X as the quotient of $\coprod X_i$ by the equivalence relation $x \sim y$ if $x = y$, or if there are i, j such that $x \in U_{ij} \subseteq X_i$, $y \in U_{ji} \subseteq X_j$, and $\varphi_{ij}(x) = y$. We take the quotient topology. Let $\psi : \coprod X_i \rightarrow X$ be the quotient map, and let $\psi_i = \psi|_{X_i}$. Now for each i we have a sheaf $\psi_* \mathcal{O}_{X_i}$ on the image of X_i by pushing forward the structure sheaf of X_i , and on the intersections, we have the pushforward of the isomorphisms $\varphi_{ij}^\#$, and these satisfy the required relation to use Ex. 2.1.22 to glue the sheaves together obtaining a sheaf \mathcal{O}_X together with isomorphisms $\psi_i^\# : \mathcal{O}_X|_{\psi_i X_i} \xrightarrow{\sim} \psi_* \mathcal{O}_{X_i}$. \square

Exercise 2.2.13. *A topological space is quasi-compact if every open cover has finite subcover.*

- (a) *Show that a topological space is noetherian if and only if every open subset is quasi-compact.*
- (b) *If X is an affine scheme show that $\text{sp}(X)$ is quasi-compact, but not in general noetherian.*
- (c) *If A is a noetherian ring, show that $\text{sp}(\text{Spec } A)$ is a noetherian topological space.*
- (d) *Give an example to show that $\text{sp}(\text{Spec } A)$ can be noetherian even when A is not.*

Proof. (a) one direction is trivial. The other direction follows from: Let U be an open subset and $\{U_i\}$ a cover of U . Define an increasing sequence of open subsets by $V_0 = \emptyset$ and $V_{i+1} = V_i \cup U_i$ where U_i is an element of the cover not contained in V_i . If we can always find such a U_i then we obtain a strictly increasing sequence of open subsets of X , which contradicts X being noetherian. Hence, there is some n for which $\bigcup_{i=1}^n U_i = U$ and therefore $\{U_i\}$ has a finite subcover.

(b) Let $\{U_i\}$ be an open cover for $\text{sp}(X)$. The complements of U_i are closed and therefore determined by ideals I_i in $A = \Gamma(\mathcal{O}_X, X)$. Since $\bigcup U_i = X$ the I_i generate the unit ideal and hence $1 = \sum_{j=1}^n f_j g_{i_j}$ for some f_j where $g_{i_j} \in I_{i_j}$. Then $\{I_{i_1}, \dots, I_{i_n}\}$ also generate the unit ideal and therefore we have a finite subcover $\{U_{i_1}, \dots, U_{i_n}\}$.

An example of a non noetherian affine scheme is $\text{Spec } k[x_1, x_2, \dots]$ which has a decreasing chain of closed subsets $V(x_1) \supseteq V(x_1, x_2) \supseteq V(x_1, x_2, x_3) \supseteq \dots$

(c) A decreasing sequence of close subsets $Z_1 \supseteq Z_2 \supseteq \dots$ corresponds to an increasing sequence $I_1 \subseteq I_2 \subseteq \dots$ of ideals of A . Since A is noetherian this stabilizes at some point and therefore, so does the sequence of closed subsets.

(d) Consider the ring $A = k[x_1, x_2, \dots] / (x_1^2, x_2^2, \dots)$. The $\text{Spec } A$ consists of only one point, since $\text{Rad}(0) = (x_1, x_2, \dots)$ is a maximal ideal. But it's not a Noetherian ring as $(x_1) \subseteq (x_1, x_2) \subseteq \dots$ in A . \square

2021.8.2 wxj

Exercise 2.2.14. (a) Let S be a graded ring. Show that $\text{Proj } S = \emptyset$ iff every element of S_+ is nilpotent.

(b) Let $\varphi : S \rightarrow T$ be a graded homomorphism of graded rings (preserving degrees). Let $U = \{p \in \text{Proj } T \mid \varphi(S_+) \not\subseteq p\}$. Show that U is an open subset of $\text{Proj } T$, and show that φ determines a natural morphism $f : U \rightarrow \text{Proj } S$.

(c) The morphism f can be a isomorphism even when φ is not. For example, suppose that $\varphi_d : S_d \rightarrow T_d$ is an isomorphism for all $d \geq d_0$, where d_0 is an integer. Then show that $U = \text{Proj } T$ and the morphism $f : \text{Proj } T \rightarrow \text{Proj } S$ is an isomorphism.

(d) Let V be a projective variety with homogeneous coordinate ring S . Show that $t(V) \simeq \text{Proj } S$.

Proof. (a) Assume that $\text{Proj } S = \emptyset$. Then any homogeneous prime ideal of S contains S_+ . Thus with the property that $\text{Rad}(0)$ is equal to the intersection of all homogeneous prime ideals of S , we can conclude that $S_+ \subseteq \text{Rad}(0)$.

Suppose that $S_+ \subseteq \text{Rad}(0)$. Let p be a homogeneous prime ideal of S . It is clear that $p \supseteq \text{Rad}(0)$ and hence $p \supseteq S_+$. Thus $\text{Proj } S = \emptyset$.

(b) Consider the set $\text{Proj } T - U = \{p \in \text{Proj } T \mid \varphi(S_+) \subseteq p\}$. For any $f \in S$, we can rewrite $f = f_1 + f_2 + \dots + f_n$ with f_i homogeneous, so $\varphi(f) = \varphi(f_1) + \dots + \varphi(f_n)$. Then the ideal generated by $\varphi(S_+)$ denoted by I is generated by the images of homogeneous elements of S which are homogeneous elements in T . So $\text{Proj } T - U = V(I)$ is closed, which means U is open.

For the map $f : U \rightarrow \text{Proj } S$, with $p \mapsto \varphi^{-1}(p)$. Since $\varphi(S_+) \not\subseteq p$ implies $S_+ \not\subseteq \varphi^{-1}(p)$. Then f is well-defined. Define a local homomorphism $\varphi_{(p)} : S_{(\varphi^{-1}(p))} \rightarrow T_{(p)}$, then $\varphi_{(p)}$ induces a morphism of sheaves $f^\# : \mathcal{O}_{\text{Proj } S} \rightarrow f_* \mathcal{O}_U$. So f is a morphism of schemes.

(c) Let $p \in \text{Proj } T$, and assume $\varphi(S_+) \subseteq p$. Take $x \in T$ homogeneous with $\deg x = \alpha > 0$. Then we can choose $n \in \mathbb{Z}$ such that $n\alpha \geq d_0$. So $x^n \in T_{n\alpha} = \varphi(S_{n\alpha}) \subseteq p$, which implies $x \in p$. Since α is any integer, we get $T_+ \subseteq p$, contradicting with $p \in \text{Proj } T$. Then $\varphi(S_+) \not\subseteq p$. Hence $U = \text{Proj } T$.

The morphism f is an isomorphism.

If $d_0 \leq 0$, φ is an isomorphism, in which case the conclusion is trivial. Thus we assume that $d_0 \geq 1$.

Firstly we show that $\{D_+^S(g) \mid \deg g \geq d_0\}$ is an open affine cover of $\text{Proj } S$. If not, assume that $p \in \text{Proj } S$ is not contained in $D_+^S(g)$, i.e. $g \in p$, for any $g \in S$ with $\deg g \geq d_0$. Then for any $x \in S_+$, $x^n \in p$ since $\deg x^n \geq d_0$ for some $n > 0$, and hence $x \in p$. Thus $S_+ \subseteq p$, which is a contradiction. Moreover since φ_d is an isomorphism for each $d \geq d_0$, $\{D_+^T(\varphi(g)) \mid g \in S, \deg g \geq d_0\}$ is an open affine cover of $\text{Proj } T$.

With the fact that $D_+^S(g) = \text{Spec } S_{(g)}$ and $D_+^T(\varphi(g)) = \text{Spec } T_{(\varphi(g))}$, by Ex. 2.2.17(a) and Ex. 2.2.18, it suffices to show that $\varphi_{(g)} : S_{(g)} \rightarrow T_{(\varphi(g))}$ is an isomorphism for any $g \in S$ with $\deg g \geq d_0$, which immediately follows the assumption that φ_d is an isomorphism for all $d \geq d_0$. \square

Exercise 2.2.15. (a) Let V be a variety over the algebraically closed field k . Show that a point $P \in t(V)$ is a closed point if and only if its residue field is k .

(b) If $f : X \rightarrow Y$ is a morphism of schemes over k , and if $P \in X$ is a point with residue field k , then $f(P) \in Y$ also has residue field k .

(c) Now show that if V, W are two varieties over k , then the natural map

$$\mathrm{Hom}_{\mathfrak{Var}}(V, W) \longrightarrow \mathrm{Hom}_{\mathfrak{Set}/k}(t(V), t(W))$$

is bijective.

Proof. □

2021.8.3 lc

Exercise 2.2.16. Let X be a scheme, let $f \in \Gamma(X, \mathcal{O}_X)$, and define X_f to be the subset of points $x \in X$ such that the stalk f_x of f at x is not contained in the maximal ideal \mathfrak{m}_x of the local ring \mathcal{O}_x .

(a) If $U = \mathrm{Spec} B$ is an open affine subscheme of X , and if $\bar{f} \in B = \Gamma(U, \mathcal{O}_X|_U)$ is the restriction of f , show that $U \cap X_f = D(\bar{f})$. Conclude that X_f is an open subset of X .

(b) Assume X is quasi-compact. Let $A = \Gamma(X, \mathcal{O}_X)$, and let $a \in A$ be an element whose restriction to X_f is 0. Show that for some $n > 0$, $f^n a = 0$.

(c) Now assume that X has a finite cover by open affines U_i such that the intersection $U_i \cap U_j$ is quasi-compact. (This hypothesis is satisfied, for example, if $\mathrm{sp}(X)$ is noetherian.) Let $b \in \Gamma(X_f, \mathcal{O}_{X_f})$. Show that for some $n > 0$, $f^n b$ is the restriction of an element of A .

(d) With the hypothesis of (c), conclude that $\Gamma(X_f, \mathcal{O}_{X_f}) \simeq A_f$.

Proof. (a) Assume $x \in D(\bar{f})$. Then $\bar{f} \notin \mathfrak{m}_x$ and hence $f_x = \bar{f}_x = \bar{f} \notin xB_x = \mathfrak{m}_x$ viewing B as a subring of B_x . Thus $D(\bar{f}) \subseteq X_f$. On the other hand, let $x \in U \cap X_f$. Then $\mathcal{O}_x = B_x$ and $\mathfrak{m}_x = xB_x$. Thus the condition that $f_x \notin \mathfrak{m}_x$ implies that $\bar{f} \notin \mathfrak{m}_x$ and hence $x \in D(\bar{f})$. Therefore, $U \cap X_f \subseteq D(\bar{f})$. Then we obtain that $U \cap X_f = D(\bar{f})$.

Let $\{U_i\}_{i \in I}$ be an open affine cover of X and let $f_i = f|_{U_i}$. Then $X_f = \bigcup_{i \in I} (U_i \cap X_f) = \bigcup_{i \in I} D_{U_i}(f_i)$ is open.

(b) Choose a finite open affine cover $\{U_i\}_{i=1}^l$ of X with $U_i = \mathrm{Spec} B_i$, and write $f_i = f|_{U_i}$ and $a_i = a|_{U_i}$. By (a), $U_i \cap X_f = D_{U_i}(f_i)$ and hence $\mathcal{O}_X(U_i \cap X_f) = (B_i)_{f_i}$. Since $a|_{X_f} = 0$, the image of a_i in $(B_i)_{f_i}$ is $a_i|_{U_i \cap X_f} = 0$, and then by the definition of localization $f_i^{n_i} a_i|_{U_i} = f_i^{n_i} a_i = 0$. Let $n = \max\{n_1, \dots, n_l\}$. We have $f^n a|_{U_i} = 0$ for all $i = 1, \dots, l$, hence $f^n a = 0$.

(c) Assume that $U_i = \mathrm{Spec} B_i$ and write $b_i = b|_{U_i \cap X_f}$. By (a), $\mathcal{O}_X(U_i \cap X_f) = (B_i)_{f_i}$, and hence we have $f_i^{k_i} b_i \in B_i$ for some $k_i > 0$ by the definition of localization. Choose the maximal k_i denoted by k . Then $f_i^k b_i \in \mathcal{O}_X(U_i)$ for all i . Let $b_{ij} = f_i^k b_i|_{U_i \cap U_j} - f_j^k b_j|_{U_i \cap U_j}$. Then $b_{ij}|_{U_i \cap U_j \cap X_f} = 0$. Since $U_i \cap U_j$ is quasi-compact, by (b), $f_{ij}^{m_{ij}} b_{ij} = 0$ for some $m_{ij} > 0$ where $f_{ij} = f|_{U_i \cap U_j}$. Choose the maximal m_{ij} denoted by m . Let $n = m + k$. Then we have that $f_i^n b_i \in B_i = \mathcal{O}_X(U_i)$ and $f_i^n b_i|_{U_i \cap U_j} = f_j^n b_j|_{U_i \cap U_j}$. Therefore there exists $t \in \Gamma(X, \mathcal{O}_X)$ such that $t|_{X_f} = f^n b$.

(d) We will use the notations in (c). By (b) and the definition of localization, it is clear that $\Gamma(X_f, \mathcal{O}_{X_f}) \subseteq A_f$. On the other hand, let $f^{-n} a \in A_f$ where $a \in A$ and $n > 0$. By (a), we can map $f^{-n} a$ into $\mathcal{O}_X(U_i \cap X_f)$ with image $s_i = f_i^{-n}(a|_{U_i})$ (this follows the universal property of localization). With the fact that $t_i|_{U_i \cap U_j \cap X_f} = f_{ij}^{-n}(a|_{U_i \cap U_j \cap X_f}) = t_j|_{U_i \cap U_j \cap X_f}$, we have that

$A_f \subseteq \ker \psi = \Gamma(X_f, \mathcal{O}_{X_f})$, where ψ is defined as:

$$\begin{array}{ccccccc}
 & & A_f & & & & \\
 & & \uparrow & \searrow & & & \\
 0 & \longrightarrow & \Gamma(X_f, \mathcal{O}_{X_f}) & \longrightarrow & \bigoplus_i \mathcal{O}_X(U_i \cap X_f) & \xrightarrow{\psi} & \bigoplus_{i,j} \mathcal{O}_X(U_i \cap U_j \cap X_f) \\
 & & \uparrow & & \uparrow & & \\
 & & A & \longrightarrow & \bigoplus_i \mathcal{O}_X(U_i) & &
 \end{array}$$

Finally, we get that $\Gamma(X_f, \mathcal{O}_{X_f}) = A_f$. \square

Exercise 2.2.17 (A Criterion for Affineness).

(a) Let $f : X \rightarrow Y$ be a morphism of schemes, and suppose that Y can be covered by open subsets U_i , such that for each i , the induced map $f^{-1}(U_i) \rightarrow U_i$ is an isomorphism. Then f is an isomorphism.

(b) A scheme X is affine if and only if there is a finite set of elements $f_1, \dots, f_r \in A = \Gamma(X, \mathcal{O}_X)$ such that the open subsets X_{f_i} are affine, and f_1, \dots, f_r generate the unit ideal in A .

Proof. (a) Topologically, the two spaces are of course isomorphic. And to check the isomorphism of sheaf structure, it suffices to check it locally.

(b) One direction is obvious. Conversely, Consider the morphism $f : X \rightarrow \text{Spec } A$. Since the f_i generate A , the principal open sets $D(f_i) = \text{Spec } A_{f_i}$ cover $\text{Spec } A$. Their pre-images are X_{f_i} , which by assumption are affine, isomorphic to $\text{Spec } A_i$. So the morphism restricts to the morphism $\varphi_i : \text{Spec } A_i \rightarrow \text{Spec } A_{f_i}$. Now we just need to show that φ_i is an isomorphism so that the result follows from part a). Equivalently, we need to show that $\varphi_i : \Gamma(X, \mathcal{O}_X)_{f_i} \rightarrow \Gamma(X_{f_i}, \mathcal{O}_X)$ is an isomorphism for each i , and the result follows from Ex. 2.2.4. The condition of Ex. 2.2.16 (d) is satisfied if the under space is Noetherian.

Injectivity:

Let $f_i^{-n}a \in A_{f_i}$ and suppose that $\varphi_i(f_i^{-n}a) = 0$. That means that it vanishes in each of the intersection $X_{f_i} \cap X_{f_j} = \text{Spec } (A_j)_{f_i}$. So for each j there is some n_j such that $f_j^{n_j}a = 0$ in A_j . Choosing m large enough, the restriction of $f_i^m a$ to each open set in a cover vanishes. So $f_i^m a = 0$ and in particular, $f_i^{-n}a = 0$ in A_{f_i} .

Surjectivity:

Let $a \in A_i$. For each $j \neq i$, we have $\mathcal{O}_X(X_{f_i f_j}) \simeq (A_j)_{f_i}$ so $a|_{X_{f_i f_j}}$ can be written as $f_i^{-n_j} b_j$ for some $b_j \in A_j$. That is, we have elements $b_j \in A_j$ whose restrictions to $X_{f_i f_j}$ is $f_i^{n_j} a$. Since there are finitely many, we can choose them so that all the n_i are the same, say n . Now on the triple intersections $X_{f_i f_j f_k} = \text{Spec } (A_j)_{f_i f_k} = \text{Spec } (A_k)_{f_i f_j}$ we have

$$b_j|_{X_{f_i f_j f_k}} - b_k|_{X_{f_i f_j f_k}} = f_i^n a - f_i^n a = 0$$

and so we can find some integer m_{jk} such that

$$f_i^{m_{jk}} (b_j|_{X_{f_j f_k}} - b_k|_{X_{f_j f_k}}) = 0.$$

Replacing each m_{jk} by a large enough m , we have a section $f_i^m b_j$ for each X_{f_j} for $j \neq i$ together with a section $f_i^{n+m} a$ on X_{f_i} and these sections all agree on intersections. This gives us a global section d whose restriction to X_{f_i} is $f_i^{n+m} a$ and so $f_i^{-n-m} d$ gets mapped to a by φ_i . \square

2021.8.9 hyx

Exercise 2.2.18. Let A, B be rings, $X = \operatorname{Spec} A$, $Y = \operatorname{Spec} B$. Let $\varphi : A \rightarrow B$ be morphisms of rings, $f : Y \rightarrow X$ be the induced morphism and $f^\# : \mathcal{O}_X \rightarrow f_* \mathcal{O}_Y$ be the map of sheaves.

- (a) For $h \in A$, show that h is nilpotent if and only if $D(h) = \emptyset$.
- (b) Show φ is injective if and only if $f^\#$ is injective. And show furthermore in that case f is dominant, i.e. $f(Y)$ is dense in X .
- (c) Show that if φ is surjective, then f is a homeomorphism of Y onto a closed subset of X , and $f^\#$ is surjective.
- (d) Prove the converse to (c), namely, if $f : Y \rightarrow X$ is a homeomorphism onto a closed subset, and $f^\# : \mathcal{O}_X \rightarrow f_* \mathcal{O}_Y$ is surjective, then φ is surjective.

Proof. (a) $D(h) = \emptyset \iff h \in \mathfrak{p}, \forall \mathfrak{p} \in \operatorname{Spec} A \iff h \in \operatorname{Rad}(0)$.

(b) Firstly, assume φ is injective. The injectivity of $f^\#$ follows the flatness of localization.

Secondly assuming $f^\#$ is injective, take the morphism of global sections and then we conclude that φ is injective.

Finally assuming that φ is injective and f is not dominant, then we have $h \in A$, such that $D(h) \cap Y = \emptyset$, and $D(h) \neq \emptyset$. i.e. for any $\mathfrak{p} \in \operatorname{Spec} B$, $h \in \varphi^{-1}(\mathfrak{p})$. So $\varphi(h) \in \operatorname{Rad}(0)$. Then there exists n , such that $\varphi(h^n) = \varphi(h)^n = 0$. Since φ is injective, $h^n = 0$. By (a), $D(h) = \emptyset$, which is a contradiction.

(c) Let $\alpha = \ker \varphi$, it is easy to check that Y is homeomorphic to $V(\alpha)$ via f and $\varphi_{\mathfrak{p}} : A_{\varphi^{-1}(\mathfrak{p})} \rightarrow B_{\mathfrak{p}}$ is surjective.

(d) Let $\alpha = \ker \varphi$, consider $\phi : A \rightarrow A/\alpha$, then φ induces $\varphi' : A/\alpha \rightarrow B$, which is injective. By (b) and (c), the induces morphism of scheme $f' : \operatorname{Spec} B \rightarrow \operatorname{Spec} A/\alpha$ is dominant, and $i : \operatorname{Spec} A/\alpha \rightarrow \operatorname{Spec} A$ induces a homeomorphism from $\operatorname{Spec} A/\alpha$ to $V(\alpha)$. By the assumption, $f = i \circ f'$ is a homeomorphism, then f' is injective. Since $f(Y)$ is closed, $f'(Y)$ is closed. Therefore $f'(Y) = \operatorname{Spec} A/\alpha$, since f' is dominant. Then f' is a homeomorphism. Consider the induced maps on stalks we derive $f'^{\#}_{\mathfrak{p}} : (A/\alpha)_{\varphi^{-1}(\mathfrak{p})} \rightarrow B_{\mathfrak{p}}$ are isomorphisms. Consequently, $f' : \operatorname{Spec} B \rightarrow \operatorname{Spec} A/\alpha$ is an isomorphism of schemes, which implies φ' is an isomorphism. \square

Exercise 2.2.19. Let A be a ring. Show that the following conditions are equivalent:

- (i) $\operatorname{Spec} A$ is disconnected;
- (ii) there exists nonzero elements $e_1, e_2 \in A$, such that $e_1^2 = e_1$, $e_2^2 = e_2$, $e_1 + e_2 = 1$ (these elements are called orthogonal idempotents);
- (iii) A is isomorphic to a direct product $A_1 \times A_2$ of two nonzero rings.

Proof. (i) \implies (ii). Assume that $\operatorname{Spec} A = U_1 \cup U_2$, with that U_1 and U_2 are disjoint open subsets. Then U_i are closed, i.e. there exist ideals I_i of A such that $U_i = V(I_i)$. Then we have $I_1 + I_2 = A$, and $I_1 I_2 \subseteq \mathfrak{p}$, for any $\mathfrak{p} \in \operatorname{Spec} A$. Then there exists $f \in I_1$, $g \in I_2$, such that $f + g = 1$. Since $fg \in \operatorname{Rad}(0)$, $(fg)^n = 0$ for some n . So the fact that $(f + g)^{2n} = 1$ implies that $cf^n + dg^n = 1$ for some $c, d \in A$ nonzero. Take $e_1 = cf^n$, $e_2 = dg^n$.

(ii) \implies (iii) Trivial.

(iii) \implies (i) Take $f = (0, 1)$, $g = (1, 0)$, then $\operatorname{Spec} A = D(f) \cup D(g)$, and $D(f) \cap D(g) = \emptyset$. \square

2.3. First Properties of Schemes.

Exercise 2.3.1. Show that a morphism $f : X \rightarrow Y$ is locally of finite type if and only if for every open affine subset $V = \operatorname{Spec} B$ of Y , $f^{-1}(V)$ can be covered by open affine subset $U_j = \operatorname{Spec} A_j$, where each A_j is a finitely generated B -algebra.

Proof. Necessity: Assume that $Y = \bigcup_i V_i$ with $V_i = \operatorname{Spec} B_i$, and pick an open cover $\{W_{ik}\}$ of $V \cap V_i$ such that W_{ik} are affine in both V and V_i . Then $W_{ik} = \operatorname{Spec} B_{f_{ik}} = \operatorname{Spec} (B_i)_{g_k}$, so $B_{f_{ik}} \simeq (B_i)_{g_k}$.

Since $f^{-1}(V_i) = \bigcup_j \text{Spec } A_{ij}$, A_{ij} is a finitely generated B -algebra, and $f_{ij} : \text{Spec } A_{ij} \rightarrow \text{Spec } B_i$ induces $\varphi : B_i \rightarrow A_{ij}$, we have that $(A_{ij})_{\varphi(g_k)}$ is a finitely generated $(B_i)_{g_k}$ -algebra. Therefore, $(A_{ij})_{\varphi(g_k)}$ is a finitely generated $B_{f_{ik}}$ -algebra, and thus a finitely generated B -algebra. Notice that $\text{Spec } (A_{ij})_{\varphi(g_k)} = D(\varphi_{ij}(g_k)) = f_{ij}^{-1}(D(g_k))$, so $f^{-1}(V) = \bigcup_{i,j,k} \text{Spec } (A_{ij})_{\varphi(g_k)}$.

Sufficiency is trivial. \square

Exercise 2.3.2. *A morphism $f : X \rightarrow Y$ is quasi-compact if there is a cover of Y by open affines V_i such that $f^{-1}(V_i)$ is quasi-compact for each i . Show that f is quasi-compact if and only if for every open affine subset $V \subseteq Y$, $f^{-1}(V)$ is quasi-compact.*

Proof. Necessity:

Lemma 1. *Assume that $V = \text{Spec } B$ is an affine open subset of Y , and that $f^{-1}(V)$ is quasi-compact, then $f^{-1}(D_V(g))$ is quasi-compact for every $g \in B$.*

Proof of Lemma 1. Pick an affine open cover of $f^{-1}(V)$, we can assume that $f^{-1}(V) = \bigcup_{i=1}^n V_i$ with $V_i = \text{Spec } A_i$. Then $f_i = f|_{V_i} : \text{Spec } A_i \rightarrow \text{Spec } B$ induces $\varphi : B \rightarrow A_i$. Then $f^{-1}(D_V(g)) = \bigcup_{i=1}^n f_i^{-1}(D_V(g)) = \bigcup_{i=1}^n D_{V_i}(\varphi(g))$ is quasi-compact, since $D_{V_i}(\varphi(g))$ is quasi-compact. \square

As a corollary of Lemma 1, we can immediately conclude that

Lemma 2. *If V is an open affine subset of Y such that $f^{-1}(V)$ is quasi-compact, then $f^{-1}(W)$ is also quasi-compact if W is an open affine subset of V .*

Let V be an open affine subset of Y . Assume that $Y = \bigcup_i V_i$ such that $V_i = \text{Spec } B_i$ and $f^{-1}(V_i)$ is quasi-compact. We can write $V \subseteq \bigcup_{i=1}^n V_i$, since V is quasi-compact. So it suffices to show that $f^{-1}(V \cap V_i)$ is quasi-compact. Pick an open affine cover $\{W_{ik}\}_k$ of $V \cap V_i$. By Lemma 2, $f^{-1}(W_{ik})$ is compact. Since V is quasi-compact and $\{W_{ik}\}_{i,k}$ is also an open affine cover of V , V can be covered by finitely many W_{ik} and hence so is $V \cap V_i$, which implies that $f^{-1}(V \cap V_i)$ is quasi-compact.

Sufficiency is trivial. \square

Exercise 2.3.3. (a) *Show that a morphism $f : X \rightarrow Y$ is of finite type if and only if it is locally of finite type and quasi-compact.*

(b) *Conclude from this fact that f is of finite type if and only if for every open affine subset $V = \text{Spec } B$ of Y , $f^{-1}(V)$ can be covered by a finite number of open affines $U_j = \text{Spec } A_j$, where A_j is a finitely generated B -algebra.*

(c) *Show also if f is of finite type, then for every open affine subset $V = \text{Spec } B \subseteq Y$, and for every open affine subset $U = \text{Spec } A \subseteq f^{-1}(V)$, A is a finitely generated B -algebra.*

Proof. (a) Necessity: Let $\{V_i\}$ be an open affine cover of Y . Then $f^{-1}(V_i) = \bigcup_{j=1}^{n_i} U_{ij}$ where U_{ij} are open affine, so $f^{-1}(V_i)$ is quasi-compact, which implies f is quasi-compact.

Sufficiency: By Ex. 2.3.2, $f^{-1}(V)$ is quasi-compact for every affine open subset V of Y .

(b) Necessity follows Ex. 2.3.1, 2.3.2 and (a), and sufficiency is trivial.

(c) Since f is of finite type, $f^{-1}(V) = \bigcup_{i=1}^n U_i$, with $U_i = \text{Spec } A_i$, where A_i are finitely generated B -algebras. Pick an open affine cover W_{ik} of $U \cap f^{-1}(U_i)$, such that W_{ik} are principle both in U and U_i , i.e. $W_{ik} = \text{Spec } A_{g_{ik}} = \text{Spec } (A_i)_{f_k}$. So $A_{g_{ik}} \simeq (A_i)_{f_k}$ are finitely generated B -algebras. Since $U = \bigcup_{i,k} W_{ik}$, and U is quasi-compact, we can pick a finite subcover of $\{W_{ik}\}$ of U , say, $U = \bigcup_{i=1}^n \bigcup_{k=1}^{l_i} W_{ik}$. Then we have $a_{ik} \in A$, such that $\sum_{i,k} a_{ik} g_{ik} = 1$. And the result comes from the following lemma:

Lemma 3. *If A_{g_k} is a finitely generated B -algebra, for any $k = 1, 2, \dots, n$, with $\sum_{k=1}^n a_k g_k = 1$, then A is also a finitely generated B -algebra.*

Proof of Lemma 3. We may assume $a_k = 1$, since $A_{a_k g_k} = A_{g_k}$. Then we assume

$$A_{g_k} = B \left[\frac{x_1^{(k)}}{g_k^{n_k}}, \frac{x_2^{(k)}}{g_k^{n_k}}, \dots, \frac{x_{s_k}^{(k)}}{g_k^{n_k}} \right].$$

And we claim that $A = B[\{x_i^{(k)}\}, \{g_k\}]$. For any $a \in A$, there exists $f_k \in B[T_1, T_2, \dots, T_{s_k}]$ such that

$$a = f_k \left(\frac{x_1^{(k)}}{g_k^{n_k}}, \frac{x_2^{(k)}}{g_k^{n_k}}, \dots, \frac{x_{s_k}^{(k)}}{g_k^{n_k}} \right).$$

We multiplies g_k of enough exponent on both side and get $ag_k^{m_k} = \bar{f}_k(x_1^{(k)}, x_2^{(k)}, \dots, x_{s_k}^{(k)})$. Set $m = \sum_k m_k$, then $(\sum g_k)^m = 1$, i.e. $\sum g_k^{m_k} l_k(g_1, g_2, \dots, g_n) = 1$. Therefore $a = \sum \bar{f}_k l_k \in B[\{x_i^{(k)}\}, \{g_k\}]$, which complete the proof. \square

Exercise 2.3.4. *Show that a morphism $f : X \rightarrow Y$ is finite if and only if for every open affine subset $V = \text{Spec } B$ of Y , $f^{-1}(V)$ is affine, equal to $\text{Spec } A$, where A is a finitely generated B -module.*

Proof. Necessity:

Lemma 4. *The morphism $f|_U : f^{-1}(V) \rightarrow V$ is also finite.*

Proof of Lemma 4. Assume $V \subseteq \bigcup_{i=1}^m V_i$, where $V_i = \text{Spec } B_i$ are affine open such that $f^{-1}(V_i) = \text{Spec } A_i$, and A_i is a finitely generated B_i -module. Write $U = f^{-1}(V)$ and $U_i = f^{-1}(V_i)$. Let $\varphi : B \rightarrow O_X(U)$ and $\varphi_i : B \rightarrow A_i$ be the homomorphisms induced by $f|_U : f^{-1}(V) \rightarrow V$ and $f|_{U_i} : \text{Spec } A_i \rightarrow V_i$.

Let $D_{V_i}(g) \subseteq V \cap V_i$ be a principle open subset of V_i for some $g \in B_i$. Then

$$D_{V_i}(g) = \text{Spec } (B_i)_g \quad \text{and} \quad f^{-1}(D_{V_i}(g)) = D_{U_i}(\varphi_i(g)) = \text{Spec } (A_i)_{\varphi_i(g)}.$$

It is clear that $(A_i)_{\varphi_i(g)}$ is a finite generated module over $(B_i)_g$. Write $V \cap V_i = \bigcup_j D_{V_i}(g_j)$. Then the open affine cover $\{D_{V_i}(g_j)\}$ of V satisfies the requirement for a finite morphism. \square

With Lemma 4, the conclusion we want is equivalent to the following proposition:

Assume that $Y = \text{Spec } B$ is affine. Then the morphism $f : X \rightarrow Y$ is finite if and only if $X = \text{Spec } A$ is also affine and A is a finitely generated B -module.

Let $\{V_i\}$ be an open affine cover of Y with $V_i = \text{Spec } B_i$ affine open such that $U_i = f^{-1}(V_i) = \text{Spec } A_i$, and A_i is a finitely generated B_i -module. Write $\varphi = f^\#(X)$ and $\varphi_i = f^\#(U_i)$.

Lemma 5. *If the principle open subset $D_Y(g) \subseteq V_i$ for some i , then $f^{-1}(D_Y(g)) = \text{Spec } (A_i)_{\varphi_i(g|_{V_i})}$ is affine and $(A_i)_{\varphi_i(g|_{V_i})}$ is a finitely generated $(B_i)_{(g|_{V_i})}$ -module.*

Proof of Lemma 5. By Ex. 2.2.16 (a),

$$D_Y(g) = D_Y(g) \cap V_i = Y_g \cap V_i = D_{V_i}(g|_{V_i}) = \text{Spec } (B_i)_{(g|_{V_i})}.$$

Thus we have $f^{-1}(D_Y(g)) = D_{U_i}(\varphi_i(g|_{V_i})) = \text{Spec } (A_i)_{\varphi_i(g|_{V_i})}$. And it is clear that $(A_i)_{\varphi_i(g|_{V_i})}$ is a finitely generated $(B_i)_{(g|_{V_i})}$ -module. \square

With Lemma 5, we may assume that V_i are principle open subset of Y with $B_i = B_{g_i}$ for some $g_i \in B$. Since Y is quasi-compact, we can assume that the cover is finite.

Lemma 6. *Assume that $Y = \text{Spec } R$ is affine and $\varphi : R \rightarrow \Gamma(X, \mathcal{O}_X)$ is the homomorphism induced by f . Then $f^{-1}(D(g)) = X_{\varphi(g)}$.*

Proof of Lemma 6. Let $\{U_i\}$ be an open affine cover of X . Then we have $(f|_{U_i})^{-1}(D(g)) = D_{U_i}(\varphi(g)|_{U_i})$. Hence by Ex. 2.2.16 (a), we have $f^{-1}(D(g)) = X_{\varphi(g)}$. \square

With Lemma 6, we have that $\{X_{\varphi(g_i)}\}$ is a finite open affine cover of X with $X_{\varphi(g_i)} = \text{Spec } A_i$. Moreover $X_{\varphi(g_i)} \cap X_{\varphi(g_j)} = X_{\varphi(g_i g_j)} = f^{-1}(D_Y(g_i g_j))$ is affine by Lemma 5, and hence $X_{\varphi(g_i)} \cap X_{\varphi(g_j)}$ is quasi-compact for each i, j . Let $A = \Gamma(X, \mathcal{O}_X)$. Then by Ex. 2.2.16 (d), $A_i = A_{\varphi(g_i)}$. With the construction of the structure sheaf from the basis, we have $A = \bigcap_i A_{\varphi(g_i)}$, which implies that $\varphi(g_1), \dots, \varphi(g_n)$ generate the unit ideal of A (this is not trivial!). By Ex. 2.2.17 (b), $X = \text{Spec } A$ is affine. With the assumption that $A_{\varphi(g_i)}$ is a finitely generated B_{g_i} -module, write $A_{\varphi(g_i)} = \varphi_i(B_{g_i})l_{i1} + \dots + \varphi_i(B_{g_i})l_{it_i}$, with $l_{i1}, \dots, l_{it_i} \in A$. Thus for any $a \in A$, we have

$$a = \frac{1}{\varphi(g_i)^{k_i}} (\varphi(b_{i1})l_{i1} + \dots + \varphi(b_{it_i})l_{it_i})$$

for each i with $k_i \in \mathbb{Z}_{\geq 0}$ and $b_{ij} \in B$ for $j = 1, \dots, t_i$. And hence

$$\varphi(g_i)^{k_i} a = \varphi(b_{i1})l_{i1} + \dots + \varphi(b_{it_i})l_{it_i}.$$

Since g_1, \dots, g_n generate the unit ideal of B , which follows the assumption that $\{D_Y(g_i)\}$ covers Y , we have $h_1 g_1 + \dots + h_n g_n = 1$ for some $h_1, \dots, h_n \in B$. Therefore,

$$\begin{aligned} a &= (\varphi(h_1)\varphi(g_1) + \dots + \varphi(h_n)\varphi(g_n))^k a \\ &= \varphi(p_1)\varphi(g_1)^{k_1} a + \dots + \varphi(p_n)\varphi(g_n)^{k_n} a \\ &= \sum_{i,j} \varphi(q_{ij})l_{ij} \end{aligned}$$

where $k = k_1 + \dots + k_n$, and each $p_i, q_{ij} \in B$. Hence we can conclude that A is a finitely generated B -module with generators $\{l_{ij}\}$. \square

8.10 wxj

Exercise 2.3.5.

Proof.

\square

Exercise 2.3.6.

Proof.

\square

Exercise 2.3.7. *A morphism $f : X \rightarrow Y$, with Y irreducible, is generically finite if $f^{-1}(\eta)$ is a finite set, where η is the generic point of Y . A morphism $f : X \rightarrow Y$ is dominate if $f(X)$ is dense in Y . Now let $f : X \rightarrow Y$ be a dominant, generically finite morphism of finite type of integral schemes. Show that there is an open dense subset $U \subseteq Y$ such that the induced morphism $f^{-1}(U) \rightarrow U$ is finite.*

Proof. This question is not easy, the following results are used which are not only listed in advance, but also stated completely as they're extremely important!!

Theorem 7 (Noether Normalization). *For any field k , and any finitely generated commutative k -algebra A , there exists a non-negative integer d and algebraically independent elements y_1, y_2, \dots, y_d in A such that A is a finitely generated module over the polynomial ring $S = k[y_1, y_2, \dots, y_d]$. (See [AM69, Ch. 5, Ex. 16, P. 69].)*

Theorem 8 (“Going-up”). *If B is an integral extension of A , then the extension satisfies the going-up property, i.e. whenever $\mathfrak{p}_1 \subseteq \mathfrak{p}_2 \subseteq \dots \subseteq \mathfrak{p}_n$ is a chain of prime ideals of A and $\mathfrak{q}_1 \subseteq \mathfrak{q}_2 \subseteq \dots \subseteq \mathfrak{q}_m$ ($m < n$) is a chain of prime ideals of B such that for each $1 \leq i \leq m$, \mathfrak{q}_i lies over \mathfrak{p}_i , then the latter chain can be extended to a chain $\mathfrak{q}_1 \subseteq \mathfrak{q}_2 \subseteq \dots \subseteq \mathfrak{q}_n$ such that for each $1 \leq i \leq n$, \mathfrak{q}_i lies over \mathfrak{p}_i . (See [AM69, Ch. 5, Th. 5.11, P. 62].)*

Lemma 9. *We say a morphism of schemes $f : X \rightarrow Y$ integral if there is an open affine sets $V_i = \text{Spec } B_i$ of Y such that, for each i , $f^{-1}(V_i) = \text{Spec } A_i$ is affine, where A_i is integral over B_i as a B_i -algebra. A morphism of schemes is finite if and only if it is of finite type and integral. (See [EGA2, Def. 6.1.1 and Prop. 6.1.4, P. 110].)*

Step 1: $k(X)$ is a finite field extension of $k(Y)$. By the condition “finite type”, we can choose an open affine $\text{Spec } B = V \subseteq Y$ and an open affine in its preimage $\text{Spec } A = U \subseteq f^{-1}(V)$ such that A is a finitely generated B -algebra. Since the function field is determined by its open set, it doesn’t matter to substitute “algebra” with “module”.

Now A is finitely generated over B and therefore $k(B) \otimes_B A$ is finitely generated over $k(B)$, where $k(B)$ is the function field of V , i.e. the quotient field of B (since Y is integral, the generic point is unique and hence $k(Y) = k(B)$). So by Theorem 7, there is an integer n and a morphism $k(B)[t_1, \dots, t_n] \rightarrow k(B) \otimes_B A$ for which $k(B) \otimes_B A$ is integral over $k(B)[t_1, \dots, t_n]$. $\text{Spec}(k(B) \otimes_B A) = \text{Spec } k(B) \times \text{Spec } A$. By the commutative diagram:

$$\begin{array}{ccc} \text{Spec } k(B) \times \text{Spec } A & \longrightarrow & \text{Spec } k(B) \\ \downarrow & & \downarrow \\ \text{Spec } A & \longrightarrow & \text{Spec } B \end{array}$$

$\text{Spec}(k(B) \otimes_B A)$ has the same underlying space as $f^{-1}(\eta_Y) \cap U$, which is finite by our assumption, and is not empty since the morphism is dominant. By Theorem 8, $\text{Spec}(k(B) \otimes_B A) \rightarrow \text{Spec}(k(B)[t_1, \dots, t_n])$ is surjective we see that $n = 0$. Then the morphism $\text{Spec } k(B) \times \text{Spec } A \rightarrow \text{Spec } k(B)$ is of finite type and integral, by Lemma 9, we can complete Step 1.

Step 2: The case where X and Y are affine. Let $X = \text{Spec } A$, and $Y = \text{Spec } B$ and consider a set of generators $\{a_i\}$ for A over B . Considered as an element of $k(A)$, each generator satisfies some polynomial in $k(B)$ since it is a finite field extension. Clearing denominators, we get a set of polynomials with coefficients in B . Let b be the product of the leading coefficients in these polynomials. Replacing B and A with B_b and A_b , all these leading coefficients become units, and so after multiplying by their inverses, we can assume that the polynomials are monic. That is, A_b is finitely generated over B_b and there is a set of generators that satisfy monic polynomials with coefficients in B_b . Hence, A_b is integral over B_b and therefore a finitely generated B_b -module.

Step 3: Since the question is local on the base, we can always assume Y is affine. Cover $f^{-1}(Y)$ with finitely many open affine subsets $U_i = \text{Spec } A_i$. By Step 2, for each i there is a dense open subsets V_i of Y such that $f^{-1}(V_i) \cap U_i \rightarrow V_i$ is finite, take $V' = \bigcap V_i$, then $f^{-1}(V') \cap U_i \rightarrow V'$ is finite for all i . Write $U_i \cap f^{-1}(V')$ as U'_i , and take a principal open affine set $U' \subseteq \bigcap U'_i$, which there are elements $a_i \in A_i$ such that $U' = \text{Spec } (A_i)_{a_i}$ for each i . Similiar to the Step 2, each A_i is finite over B , there are monic polynomials g_i with coefficients in B that the a_i satisfy. Take g_i of smallest

possible degree so that the constant terms b_i are nonzero and define $b = \prod b_i$. Now the preimage of $\text{Spec } B_b$ is $\text{Spec } ((A_i)_{a_i})_b$ (any i gives the same open) and $((A_i)_{a_i})_b$ is a finitely generated B_b module. So we are done.

We can also get a similar proposition in [TS, Tag 02NW], which states that the result holds if f is quasi-compact and quasi-separated, locally of finite type between two arbitrary schemes. \square

Exercise 2.3.8 (Normalization). *A scheme is normal if all of its local rings are integrally closed domains. Let X be an integral scheme. For each open affine subset $U = \text{Spec } A$ of X , let \tilde{A} be the integral closure of A in its quotient field, and let $\tilde{U} = \text{Spec } \tilde{A}$. Show that one can glue the schemes \tilde{U} to obtain a normal integral scheme \tilde{X} called the normalization of X . Show also that there is a morphism $\tilde{X} \rightarrow X$ having the following universal property: for every normal integral scheme Z , and for every dominant morphism $f : Z \rightarrow X$, f factors uniquely through \tilde{X} . If X is of finite type over a field k , then the morphism $\tilde{X} \rightarrow X$ is a finite morphism.*

Proof. We can check they can be patched directly, but I want to give a more advanced construction from [TS] so that we can deal with more general schemes.

Lemma 10. *Let X be a scheme. Let \mathcal{A} be a quasi-coherent sheaf of \mathcal{O}_X -algebras. The subsheaf $\mathcal{A}' \subset \mathcal{A}$ defined by the rule*

$$U \longmapsto \{f \in \mathcal{A}(U) \mid f_x \in \mathcal{A}_x \text{ integral over } \mathcal{O}_{X,x} \text{ for all } x \in U\}$$

is a quasi-coherent \mathcal{O}_X -algebra, the stalk \mathcal{A}'_x is the integral closure of $\mathcal{O}_{X,x}$ in \mathcal{A}_x , and for any affine open $U \subseteq X$ the ring $\mathcal{A}'(U) \subseteq \mathcal{A}(U)$ is the integral closure of $\mathcal{O}_X(U)$ in $\mathcal{A}(U)$. (See [TS, Tag 035F]).

Definition 11. *Let $f : Y \rightarrow X$ be a quasi-compact and quasi-separated morphism of schemes. Let \mathcal{O}' be the integral closure of \mathcal{O}_X in $f_*\mathcal{O}_Y$. The normalization of X in Y is the scheme*

$$\nu : X' = \underline{\text{Spec}}_X(\mathcal{O}') \longrightarrow X$$

over X . It comes equipped with a natural factorization (by the property of relative spectra)

$$Y \xrightarrow{f'} X' \xrightarrow{\nu} X$$

of the initial morphism f .

Next, we come to the normalization of a scheme X . We only define/construct it when X has locally finitely many irreducible components. Let X be a scheme such that every quasi-compact open has finitely many irreducible components. Let $X^{(0)} \subseteq X$ be the set of generic points of irreducible components of X . Let

$$f : Y = \coprod_{\eta \in X^{(0)}} \text{Spec } \kappa(\eta) \longrightarrow X$$

be the inclusion of the generic points into X using the canonical maps of schemes. We define the normalization of X as the morphism

$$\nu : X^\nu \longrightarrow X$$

which is the normalization of X in the morphism $f : Y \rightarrow X$ constructed above.

For a normal integral scheme Z and a dominant morphism $f : Z \rightarrow X$, since a morphism of integral schemes f is dominant iff for all nonempty affine opens $U \subseteq X$ and $V \subseteq Z$ with $f(V) \subseteq U$

the ring map $\mathcal{O}_Y(V) \rightarrow \mathcal{O}_X(U)$ is injective, and the minimal normal ring contained $\mathcal{O}_X(U)$ is its normalization in its fractional field, so f factorizes through ν .

If X is of finite type over a field k , there exists a affine cover $\{\text{Spec } A_i\}$, where A_i are all finitely generated k -algebra. The morphism $\tilde{X} \rightarrow X$ is a finite morphism followed by the proposition that the integral closure A of a finitely generated k -algebra A is a finitely generated A -module. \square

8.17 hyx

Exercise 2.3.9 (The Topological Space of a Product). *Recall that in the category of varieties, the Zariski topology on the product of two varieties is not equal to the product topology. Now we see that in the category of schemes, the underlying point set of a product of schemes is not even the product set.*

(a) Let k be a field, $\mathbb{A}_k^1 = \text{Spec } k[x]$. Show $\mathbb{A}_k^1 \times_{\text{Spec } k} \mathbb{A}_k^1 \cong \mathbb{A}_k^2$. And show that the underlying point set of the product is not the product of the underlying point sets of the factors. (even if k is algebraically closed.)

(b) Let k be a field, let s, t be indeterminates over k . Then $\text{Spec } k(s)$, $\text{Spec } k(t)$, and $\text{Spec } k$ are all one-point spaces. Describe the product scheme $\text{Spec } k(s) \times_{\text{Spec } k} \text{Spec } k(t)$.

Proof. (a) $\mathbb{A}_k^1 \times_{\text{Spec } k} \mathbb{A}_k^1 \simeq \text{Spec}(k[x_1] \otimes_k k[x_2]) \simeq \mathbb{A}_k^2$.

There is a natural map of sets $\mathbb{A}_k^1 \times \mathbb{A}_k^1 \rightarrow \mathbb{A}_k^2$ by sending $(f(x)k[x], g(x)k[x])$ to $f(x_1)k[x_1, x_2] + g(x_2)k[x_1, x_2]$, which is not surjective. However, I have no idea about whether the cardinalities of these two sets are equal.

(b) $\text{Spec } k(s) \times_{\text{Spec } k} \text{Spec } k(t) = \text{Spec}(k(s) \otimes_k k(t))$.

Let

$$R = \left\{ \frac{f(s, t)}{g(s)h(t)} \mid f \in k[s, t], g \in k[s] \text{ and } h \in k[t] \right\}.$$

Then we have that $k(s) \otimes_k k(t) \simeq R$ is a integral domain but is not a field. Hence $\#(\text{Spec } k(s) \times_{\text{Spec } k} \text{Spec } k(t)) = \#\text{Spec}(k(s) \otimes_k k(t)) > 1$. \square

Exercise 2.3.10 (Fibres of a Morphism).

(a) If $f : X \rightarrow Y$ is a morphism, and $y \in Y$ a point, show that $\text{sp}(X_y)$ is homeomorphic to $f^{-1}(y)$ with the induced topology.

(b) Let $X = \text{Spec } k[s, t]/(s - t^2)$, let $Y = \text{Spec } k[s]$, and $f : X \rightarrow Y$ be the morphism defined by sending $s \rightarrow s$. If $y \in Y$ is the point $a \in k$ with $a \neq 0$, show that X_y consists of two points, with residue field k . If $y \in Y$ corresponds to $0 \in k$, show that the fibre X_y is a nonreduced one-point scheme. If η is the generic point of Y , show that X_η is a one-point scheme, whose residue field is an extension of degree two of the residue field of η . (Assume k algebraically closed.)

Proof. (a) We first prove the proposition in the case when X, Y are affine. Assume $Y = \text{Spec } A$ and $X = \text{Spec } B$. Then y is a prime ideal of A . And f induces $\varphi : A \rightarrow B$. Then $k(y) = A_y/\mathfrak{m}_y$, and $X_y = \text{Spec}(B \otimes_A k(y))$. We define B_y to be $S^{-1}B$, where $S = A - y$, a multiplicative closed set. So B_y is an A_y -module, and thus an A -module. Notice that for A -module C , $S^{-1}C \simeq S^{-1}A \otimes_A C$ (See [AM69, Ch. 3, Prop. 3.5, P. 39]). So

$$\begin{aligned} B \otimes_A k(y) &= B \otimes_A (A_y \otimes_A (A/y)) = (B \otimes_A S^{-1}A) \otimes_A (A/y) \\ &= B_y \otimes_A (A/y) = (B_y \otimes_A A)/(B_y \otimes_A y) = B_y/\varphi(y)B_y. \end{aligned}$$

Thus we have a natural morphism $h : X_y = \text{Spec}(B_y/\varphi(y)B_y) \rightarrow \text{Spec } B$, which splits as $\theta \circ j$:

$$X_y = \text{Spec}(B_y/\varphi(y)B_y) \xrightarrow{j} \text{Spec } B_y \xrightarrow{\theta} \text{Spec } B \xrightarrow{f} \text{Spec } A$$

which are induced by homomorphisms:

$$A \xrightarrow{\varphi} B \xrightarrow{i} B_y \xrightarrow{\pi} B_y/\varphi(y)B_y.$$

And j is a closed immersion mapping X_y onto $V(\varphi(y)B_y) \subseteq \text{Spec } B_y$ by Ex. 2.3.11 (b), so it suffices to check:

$$(1) \theta(V(\varphi(y)B_y)) = f^{-1}(y); (2) \theta|_{V(\varphi(y)B_y)} \text{ is injective}; (3) \theta|_{V(\varphi(y)B_y)} \text{ is closed}.$$

Proof of (1). The fact that

$$\theta(V(\varphi(y)B_y)) = \{i^{-1}(\mathfrak{q}) \mid \mathfrak{q} \in \text{Spec } B_y, \varphi(y)B_y \subseteq \mathfrak{q}\}$$

implies that $f(i^{-1}(\mathfrak{q})) = \varphi^{-1}(i^{-1}(\mathfrak{q})) \supseteq y$. For any $a \in A - y$, $i(\varphi(a))$ is a unit of B_y , which is not contained in \mathfrak{q} , so we have $f(i^{-1}(\mathfrak{q})) = \varphi^{-1}(i^{-1}(\mathfrak{q})) \subseteq y$. Then we have $f(i^{-1}(\mathfrak{q})) = \varphi^{-1}(i^{-1}(\mathfrak{q})) = y$. Hence $\theta(V(\varphi(y)B_y)) \subseteq f^{-1}(y)$.

For any $z \in f^{-1}(y)$, i.e. $\varphi^{-1}(z) = y$, we want to find $\mathfrak{q} \supseteq \varphi(y)B_y$, such that $i^{-1}(\mathfrak{q}) = z$. And we claim that $\mathfrak{q} = i(z)B_y$ satisfies the condition. Firstly, since $z \supseteq \varphi(p)$, we have $\mathfrak{q} \supseteq \varphi(y)B_y$. Secondly, since $B_y/\mathfrak{q} = (B/z) \otimes_B B_y$ is some localization of an integral domain and hence is also an integral domain, \mathfrak{q} is a prime. Thirdly, it is clear that $i^{-1}(\mathfrak{q}) = z$. \square

Proof of (2). By the claim in the proof of (1), we have $\mathfrak{q} = i(i^{-1}(\mathfrak{q}))B_y$, which implies the injectivity. \square

Proof of (3). For any $\frac{b}{d} \in B_y$, By (1) we have

$$\begin{aligned} \theta \left(V(\varphi(y)B_y) \cap V \left(\frac{b}{d} \right) \right) &= \left\{ i^{-1}(\mathfrak{q}) \mid \varphi(y)B_y \subseteq \mathfrak{q}, \frac{b}{d} \in \mathfrak{q} \right\} \\ &= \{ i^{-1}(\mathfrak{q}) \mid \varphi(y)B_y \subseteq \mathfrak{q}, b \in \mathfrak{q} \} \\ &= \{ z \mid \varphi(y) \subseteq z, b \in z \}, \end{aligned}$$

which is closed. \square

Then we can conclude that $\theta \circ j$ is the homeomorphism from X_y onto $f^{-1}(y)$. In fact, $\theta \circ j$ is the natural projection $X_y = X \times_Y \text{Spec } k(y) \rightarrow X$.

Now for general cases, we need the following lemma:

Lemma 12. Assume that $f : X \rightarrow Y$, $i : Z \rightarrow Y$ are morphisms of schemes, $V \subseteq Y$ is open, and $i(Z) \subseteq V$. Then $X \times_Y Z \simeq f^{-1}(V) \times_V Z$.

Proof of Lemma 12. Let $p_1 : X \times_Y Z \rightarrow X$ and $p_2 : X \times_Y Z \rightarrow Z$ be the natural projections. The fact that

$$(f \circ p_1)(X \times_Y Z) = (i \circ p_2)(X \times_Y Z) \subseteq i(Z) \subseteq V$$

implies $p_1(X \times_Y Z) \subseteq f^{-1}(V)$. Thus we have the following commutative diagram.

Then we can get our conclusion from this diagram. \square

Then we choose $V = \text{Spec } A \subseteq Y$, such that $y \in \text{Spec } A$, and assume $f^{-1}(V) = \bigcup_i \text{Spec } B_i$. So by Lemma 12,

$$\begin{aligned} X_y &= f^{-1}(V) \times_V \text{Spec } k(y) \\ &= \left(\bigcup \text{Spec } B_i \right) \times_{\text{Spec } A} \text{Spec } k(y) \\ &= \bigcup (\text{Spec } B_i \times_{\text{Spec } A} \text{Spec } k(y)). \end{aligned}$$

Let $\text{Spec } B_i \times_{\text{Spec } A} \text{Spec } k(y) = U_i$, and let p be the natural projection from X_y to X . By The proof of affine cases, $p|_{U_i}$ is a homeomorphism from U_i onto $(f|_{\text{Spec } B_i})^{-1}(y)$, so p is also a homeomorphism mapping X_y onto $f^{-1}(y)$ by Ex. 2.2.17 (a).

(b) Trivial. \square

2021.8.18 ysh

Exercise 2.3.11 (Closed Subschemes).

(a) *Closed immersions are stable under base extension: if $f : Y \rightarrow X$ is a closed immersion, and if $g : X' \rightarrow X$ is any morphism, then $f' : Y \times_X X' \rightarrow X'$ is also a closed immersion.*

(b) *If Y is a closed subscheme of an affine scheme $X = \text{Spec } A$, then Y is also affine, and in fact Y is the closed subscheme determined by a suitable ideal $\mathfrak{a} \subseteq A$ as the image of the closed immersion $\text{Spec } A/\mathfrak{a} \rightarrow \text{Spec } A$. Note: We will give another proof of this result using sheaves of ideals later (Corollary 2.5.10).*

(c) *Let Y be a closed subset of a scheme X , and give Y the reduced induced subscheme structure. If Y' is any other closed subscheme of X with the same underlying topological space, show that the closed immersion $Y \rightarrow X$ factors through Y' . We express this property by saying that the reduced induced structure is the smallest subscheme structure on a closed subset.*

(d) *Let $f : Z \rightarrow X$ be a morphism. Then there is a unique closed subscheme Y of X with the following property: the morphism f factors through Y , and if Y' is any other closed subscheme of X through which f factors, then $Y \rightarrow X$ factors through Y' also. We call Y the scheme-theoretic*

image of f . If Z is a reduced scheme, then Y is just the reduced induced structure on the closure of the image $f(Z)$.

Proof. (a) The result follows immediately once we have (b). Suppose that we have proven (b). Firstly, assume that $X = \operatorname{Spec} A$, and $X' = \operatorname{Spec} B$. Then $Y = \operatorname{Spec} A/I$, and the morphism $Y \times_X X' \rightarrow X'$ is induced by the surjective homomorphism $B \rightarrow B \otimes_A (A/I) = B/IB$; it is therefore a closed immersion.

Then we consider the general case. Since the property of sheaves of closed immersion is local on X , we only need to prove the topological property. Let $\{V_i\}_i$ be an open affine cover of X with $V_i = \operatorname{Spec} A_i$ and write $U_i = f^{-1}(V_i)$. Then for each i , $f|_{U_i} : f^{-1}(V_i) \rightarrow V_i$ is also a closed immersion, and hence by (b), U_i is affine. Let $\{W_{ij}\}_{i,j}$ be an affine open cover of $g^{-1}(V_i)$. Then we get an affine open cover $\{W_{ij}\}_{i,j}$ of X' such that $g(W_{ij}) \subseteq V_i$. By Lemma 12, we have

$$f'^{-1}(W_{ij}) = Y \times_X W_{ij} \simeq U_i \times_{V_i} W_{ij}$$

is affine, and moreover $\{Y \times_X W_{ij}\}_{i,j}$ is an open affine cover of $Y \times_X X'$. Hence $f'|_{Y \times_X W_{ij}} : Y \times_X W_{ij} \rightarrow W_{ij}$ is a closed immersion for each i, j . With the discussion above, it is easy to get that f' is a closed immersion.

(b) We use a method based on the mentioned “sheaf of ideals”. In fact all the followings come from [Liu02, Ch. 2, Prop. 3.20, P. 47]. See [GW10, Ch. 3, Th. 3.42, P. 84] and [Sha13, P. 32] for other proofs. First we need some lemmas.

Lemma 13. *Let (X, \mathcal{O}_X) be a ringed topological space. Let \mathcal{J} be a sheaf of ideals of \mathcal{O}_X (i.e., $\mathcal{J}(U)$ is an ideal of $\mathcal{O}_X(U)$ for every open subset U). Let $V(\mathcal{J}) := \{x \in X \mid \mathcal{J}_x \neq \mathcal{O}_{X,x}\}$. Let $j : V(\mathcal{J}) \rightarrow X$ denote the inclusion. Then $V(\mathcal{J})$ is a closed subset of X , $(V(\mathcal{J}), j^{-1}(\mathcal{O}_X/\mathcal{J}))$ is a ringed topological space, and we have a closed immersion $(j, j^\#)$ of this space into (X, \mathcal{O}_X) , where $j^\#$ is the canonical surjection*

$$\mathcal{O}_X \longrightarrow \mathcal{O}_X/\mathcal{J} = j_* (j^{-1}(\mathcal{O}_X/\mathcal{J}))$$

Proof of Lemma 13. If $x \in X \setminus V(\mathcal{J})$, there exist an open neighborhood $U \ni x$ and $f \in \mathcal{J}(U)$ such that $f_x = 1$. It follows that $f|_V = 1$ in an open neighborhood $V \subseteq U$ of x . We then have $V \subseteq X \setminus V(\mathcal{J})$. The latter is therefore open. For every $x \in V(\mathcal{J})$, $(j^{-1}(\mathcal{O}_X/\mathcal{J}))_x = (\mathcal{O}_X/\mathcal{J})_x = \mathcal{O}_{X,x}/\mathcal{J}_x$ is a local ring. The rest follows immediately. \square

Lemma 14. *Let $f : Y \rightarrow X$ be a closed immersion of ringed topological spaces. Let Z be the ringed topological space $V(\mathcal{J})$ where $\mathcal{J} = \ker f^\# \subseteq \mathcal{O}_X$. Then f factors into an isomorphism $Y \simeq Z$ followed by the canonical closed immersion $Z \rightarrow X$.*

Proof of Lemma 14. As $f(Y)$ is closed in X , we have

$$(f_*\mathcal{O}_Y)_x = \begin{cases} 0 & \text{if } x \notin f(Y) \\ \mathcal{O}_{Y,y} & \text{if } x = f(y) \end{cases}$$

Using the exact sequence $0 \rightarrow \mathcal{J} \rightarrow \mathcal{O}_X \rightarrow f_*\mathcal{O}_Y \rightarrow 0$, we deduce that $\mathcal{J}_x = \mathcal{O}_{X,x}$ if and only if $x \notin f(Y)$, whence the equality of sets $V(\mathcal{J}) = f(Y)$. Let $j : Z \rightarrow X$ be the canonical injection. Let $g : Y \rightarrow Z$ be the homeomorphism induced by f . Then $f = j \circ g$ as maps and $j_*\mathcal{O}_Z = \mathcal{O}_X/\mathcal{J} \simeq f_*\mathcal{O}_Y$. We show without difficulty that $f_*\mathcal{O}_Y = j_*g_*\mathcal{O}_Y$. It follows that $\mathcal{O}_Z = j^{-1}j_*\mathcal{O}_Z \simeq j^{-1}j_*g_*\mathcal{O}_Y = g_*\mathcal{O}_Y$, whence an isomorphism of ringed topological spaces $g : Y \xrightarrow{\sim} Z$. And it is easy to verify that $f = j \circ g$ as morphisms of ringed topological spaces. \square

We denote the closed immersion of Y into X by j . Let us first show that Y verifies condition in Ex. 2.2.16 (b). There exist open subsets U_p of X such that $\{j^{-1}(U_p)\}_p$ is an affine open covering of Y . Each U_p is a union of principal open subsets $\{U_{pk}\}_k$ of X , and $j^{-1}(U_{pk})$ is affine because it is a principal open subset of $j^{-1}(U_p)$. By adding principal open sets covering $X \setminus j(Y)$, we obtain (since X is quasi-compact) a covering of X by a finite number of principal open sets $\{V_l\}_l$ such that $j^{-1}(V_l)$ is affine for every l . As $j^{-1}(V_l) \cap j^{-1}(V_{l'})$ is a principal open subset of $j^{-1}(V_l)$, and therefore affine, we indeed have the condition.

Let $\mathcal{J} = \ker j^\#$ and $\mathfrak{a} = \mathcal{J}(X)$. We know that Y is isomorphic to $V(\mathcal{J})$ endowed with the sheaf $\mathcal{O}_X/\mathcal{J}$ (Lemma 13). Let $g \in A$. We let h denote the image of g in $\mathcal{O}_Y(Y)$. From the exact sequence $0 \rightarrow \mathfrak{a} \rightarrow A \rightarrow \mathcal{O}_Y(Y)$, we deduce an exact sequence by $\otimes_A A_g : 0 \rightarrow \mathfrak{a} \otimes_A A_g \rightarrow A_g = \mathcal{O}_X(D(g)) \rightarrow \mathcal{O}_Y(Y)_h$. Now $\mathcal{O}_Y(Y)_h = \mathcal{O}_Y(Y_h) = j_* \mathcal{O}_Y(D(g))$ (Ex. 2.2.16); therefore we have $\mathcal{J}(D(g)) = \mathfrak{a} \otimes_A A_g$. Let $i : \text{Spec } A/J \rightarrow X$ be the closed immersion defined canonically. Then $(\ker i^\#)(D(g)) = \mathcal{J}(D(g))$ for every principal open subset $D(g)$ of X . It follows that $\ker i^\# = \mathcal{J}$. Hence $Y \simeq \text{Spec } A/\mathfrak{a}$. \square

Exercise 2.3.12 (Closed Subschemes of $\text{Proj } S$).

(a) Let $\varphi : S \rightarrow T$ be a surjective homomorphism of graded rings, preserving degrees. Show that the open set U of (Ex. 2.2.14) is equal to $\text{Proj } T$, and the morphism $f : \text{Proj } T \rightarrow \text{Proj } S$ is a closed immersion.

(b) If $I \subseteq S$ is a homogeneous ideal, take $T = S/I$ and let Y be the closed subscheme of $X = \text{Proj } S$ defined as the image of the closed immersion $\text{Proj } S/I \rightarrow X$. Show that different homogeneous ideals can give rise to the same closed subscheme. For example, let d_0 be an integer, and let $I' = \bigoplus_{d \geq d_0} I_d$. Show that I and I' determine the same closed subscheme.

We will see later (Corollary 2.5.16) that every closed subscheme of X comes from a homogeneous ideal I of S (at least in the case where S is a polynomial ring over S_0).

Proof. (a) Recall that $U = \{\mathfrak{p} \in \text{Proj } T \mid \mathfrak{p} \not\supseteq \varphi(S_+)\}$. Since the morphism is surjective, we have $\varphi(S_+) = T_+$, and hence $\mathfrak{p} \not\supseteq \varphi(S_+) \iff \mathfrak{p} \not\supseteq T_+$. So by Ex. 2.2.14, we have a natural morphism $f : \text{Proj } T \rightarrow \text{Proj } S$. Actually, it is defined by $\mathfrak{p} \mapsto \varphi^{-1}(\mathfrak{p})$.

Check the sheaf of structure: since the map on stalks is the same as the localization map $\varphi(p) : S_{(\mathfrak{p})} \rightarrow T \otimes_S S_{(\mathfrak{p})}$, which is surjective since φ is surjective.

Check the space: claim $f(\text{Proj } T) = V(\mathfrak{a})$, where

$$\mathfrak{a} = \bigcap_{\mathfrak{p} \in \text{Proj } T} \varphi^{-1}(\mathfrak{p}).$$

Obviously, $f(\text{Proj } T) \subseteq V(\mathfrak{a})$. For the inverse, let $\mathfrak{q} \supseteq \mathfrak{a}$ and let \mathfrak{q}' be the inverse image of the minimal prime ideal containing $\varphi(\mathfrak{q})$. It suffices to check that $\mathfrak{q} = \mathfrak{q}'$. Actually, since the morphism is surjective, the minimal prime ideal containing $\varphi(\mathfrak{q})$ is just $\varphi(\mathfrak{q})$, which is a homogeneous ideal. By definition, $\mathfrak{q}' \supseteq \mathfrak{q}$. If the inclusion is proper, pick $x \in \mathfrak{q}' \setminus \mathfrak{q}$, there exists $y \in \mathfrak{q}$ such that $\varphi(x) = \varphi(y)$, then $x - y \in \mathfrak{q}' \setminus \mathfrak{q}$ and $\varphi(x - y) = 0$, so $x - y \in \mathfrak{a}$ which is a contradiction and thus $\mathfrak{q}' = \mathfrak{q}$.

(b) Let $I \subseteq S$ be a homogeneous ideal and let $T = S/I$. Let Y be the closed subscheme of $X = \text{Proj } S$ defined as the image of the closed immersion $\text{Proj } S/I \rightarrow X$. There is a commutative

diagram of graded rings where the maps are projections:

$$\begin{array}{ccc} S & \longrightarrow & S/I' \\ \downarrow & \swarrow & \\ S/I & & \end{array}$$

This corresponds to a commutative diagrams of schemes:

$$\begin{array}{ccc} \text{Proj } S & \longleftarrow & \text{Proj } S/I' \\ \uparrow & \nearrow & \\ \text{Proj } S/I & & \end{array}$$

The map $S/I' \rightarrow S/I$ is an isomorphism for degree $d \geq d_0$, so by Ex. 2.2.14 (c), the map $\text{Proj } S/I \rightarrow \text{Proj } S/I'$ is an isomorphism. The commutative diagram shows that I and I' determine the same closed subscheme. \square

2022/3/7 HYY

Exercise 2.3.13.

Exercise 2.3.14. *If X is a scheme of finite type over a field, show that the closed points of X are dense. Give an example to show that this is not true for arbitrary schemes.*

Proof. (1) Let $\{U_i\}$ be a finite affine open cover of X , where $U_i = \text{Spec } R_i$ with R_i of finite type over a field k , and $S = \{\text{closed points of } X\}$. If $S \cap U_i$, the closed points of U_i , is dense in U_i for each i , then we have $\bar{S} \supseteq \overline{S \cap U_i} \supseteq U_i$, for each i , and hence $\bar{S} = X$.

Therefore it suffices to prove for the case that $X = \text{Spec } R$, where R is a finitely generated k -algebra. If $V(I)$ is a closed subset of X with $S \subseteq V(I)$, then $I \subseteq \bigcap_{\mathfrak{m}} \mathfrak{m} = \text{rad}(0) \subseteq \mathfrak{p}$ (see [AM69, Ch. 1, Ex. 4, P. 11] for the first equality) for all prime ideals \mathfrak{p} of R , where \mathfrak{m} ranges over all maximal ideals of R . So $V(I) = X$, showing that S is dense in X .

(2) For general cases, consider $X = \text{Spec } k[x]_{(x)}$, which is a local ring. Then the only closed point is (x) . Furthermore, we have $X = \{(0), (x)\}$. Clearly $\overline{\{x\}} = \{x\} \subsetneq X$. \square

Remark 15. I think the p -adic integer ring \mathbb{Z}_p and the formal power series ring $k[[x]]$ are better choices for the counter-example. Moreover, without the condition “quasi-compact” implied by the condition “of finite type”, we can find a scheme without closed points (see [Liu02, Ch. 3, Ex. 3.27, P. 114]).

Exercise 2.3.15. *Let X be a scheme of finite type over a field k (not necessarily algebraically closed).*

(a) *Show that the following three conditions are equivalent (in which case we say that X is geometrically irreducible).*

(i) $X \times_k \bar{k}$ is irreducible, where \bar{k} denotes the algebraic closure of k . (By abuse of notation, we write $X \times_k \bar{k}$ to denote $X \times_{\text{Spec } k} \text{Spec } \bar{k}$.)

(ii) $X \times_k k_s$ is irreducible, where k_s denotes the separable closure of k .

(iii) $X \times_k K$ is irreducible for every extension field K of k .

(b) *Show that the following three conditions are equivalent (in which case we say X is geometrically reduced).*

(i) $X \times_k \bar{k}$ is reduced.

- (ii) $X \times_k k_p$ is reduced, where k_p denotes the perfect closure of k .
- (iii) $X \times_k K$ is reduced for all extension fields K of k .
- (c) We say that X is geometrically integral if $X \times_k \bar{k}$ is integral. Give examples of integral schemes which are neither geometrically irreducible nor geometrically reduced.

Proof. This proof is based on [Liu02, P. 89-91].

Lemma 16. *Let X be an algebraic variety over k , and let K/k be an algebraic extension. Then for any reduced closed subvariety W of $X_K = X \times_k K$, there exists a finite subextension K' of K and a unique (for fixed K') reduced closed subvariety Z of $X_{K'}$ such that $W = Z_K$.*

Proof of Lemma 16. Let us first suppose that $X = \text{Spec } A$. Then $W = V(I)$, where I is a radical ideal of A_K , generated by f_1, \dots, f_m . There exists a finite subextension K' of K such that $f_i \in A_{K'}$ for every i . Let I' be the ideal of $A_{K'}$ generated by the f_i , and $Z = \text{Spec } A_{K'}/I'$. Then $I = I' \otimes_{K'} K$, and hence $Z_K = W$. We have Z is reduced, because $\mathcal{O}_Z(Z) \hookrightarrow \mathcal{O}_Z(Z) \otimes_{K'} K = \mathcal{O}_W(W)$. As the underlying space of Z is fixed (it is the image of W under the projection $X_K \rightarrow X_{K'}$, see [Liu02, Ch. 3, Ex. 1.8, P.86]), the uniqueness of the scheme structure on Z results from Ex. 2.2.3. Let us note that if (Z, K') fulfills the requirements, then so does (Z_L, L) for any finite subextension L/K' of K/K' .

In the general case, we cover X with a finite number of affine open subvarieties X_i . There then exist a finite subextension K'/k of K and reduced closed subvarieties Z_i of $(X_i)_{K'}$ such that $(Z_i)_K = W \cap (X_i)_K$. By the uniqueness in the affine case, the Z_i glue to a reduced closed subvariety Z of $X_{K'}$. We indeed have $Z_K = W$, and the uniqueness of Z comes from Ex. 2.2.3, as in the affine case. \square

- (a) It is clear that (iii) \implies (i).

Lemma 17. *Let X be an algebraic variety over k , and let K/k be an algebraic extension. If K/k is purely inseparable, then the projection $p : X_K \rightarrow X$ is a homeomorphism.*

Proof of Lemma 17. We may assume that $X = \text{Spec } A$, without loss of generality.

Firstly suppose that K is a simple extension of k . We then have $K = k[T]/(T^q - c)$, with $c \in k$ and q is a power of $\text{char } k$. Let \mathfrak{p} be a prime ideal of A . Let \mathfrak{q} be a prime ideal of $A_K = A \otimes_k K$ such that $\mathfrak{q} \cap A = \mathfrak{p}$ by Theorem 8. Then $\mathfrak{p}A_K \subseteq \mathfrak{q}$. On the other hand, since $\alpha^q \in A \cap \mathfrak{q} = \mathfrak{p}$ for all $\alpha \in \mathfrak{q}$, we have $\mathfrak{q} \subseteq \text{Rad}(\mathfrak{p}A_K)$. Hence $\mathfrak{q} = \text{Rad}(\mathfrak{p}A_K)$ and p is injective. Let us now show that p is a closed map. Let I be an ideal of A_K . Let $J = I \cap A$. Then $I^q \subseteq J$. This implies that $p(V(I)) = V(J)$. As $X_K \rightarrow X$ is surjective (Theorem 8), p is a homeomorphism.

Let us now take K/k finite. The extension K/k is made up of successive simple extensions, and therefore $X_K \rightarrow X$ is a homeomorphism by the simple case. The general case immediately follows from the finite case and Lemma 16. \square

(i) \iff (ii): This immediately follows from that the projection $X_{\bar{k}} \rightarrow X_{k_s}$ is a homeomorphism by Lemma 17.

(i) \implies (iii): Here we only consider the case that K/k is algebraic. See [TS, Tag 0364 Lemma 33.8.8] for the general case. This follows from that the projection $X_{\bar{k}} \rightarrow X_K$ is surjective.

- (b) It is clear that (iii) \implies (i).

Lemma 18. *Let X be an algebraic variety over k , and let K/k be an algebraic extension. If X is reduced and K/k is separable, then X_K is reduced.*

Proof of Lemma 18. We may assume that $X = \operatorname{Spec} A$, without loss of generality. Let $\mathfrak{p}_1, \dots, \mathfrak{p}_n$ be the minimal prime ideals of A . Then A injects into $\bigoplus_i A/\mathfrak{p}_i$, and therefore A_K injects into $\bigoplus_i (A/\mathfrak{p}_i)_K$. We can therefore assume A to be integral. As A_K is a subring of $\operatorname{Frac}(A) \otimes_k K$, it suffices to show that $F \otimes_k K$ is reduced for any field F containing k . Every element of $F \otimes_k K$ is contained in $F \otimes_k K'$, with K' finite separable over k , and we can therefore assume K to be finite over k . It follows that $K = k[T]/(P(T))$, where $P(T) \in k[T]$ is a separable polynomial. As $P(T)$ is still separable in $F[T]$, $F \otimes_k K \simeq F[T]/(P(T))$ is reduced. \square

The part (i) \iff (ii) immediately follows from Lemma 18.

(i) \implies (iii): Here we only consider the case that K/k is algebraic. See [TS, Tag 035U Lemma 33.6.4] for the general case. The algebraic case follows from Lemma 16.

(c) Let $k = \mathbb{F}_p(T)$ and $K = \mathbb{F}_p(T^{1/p})$. Then $\operatorname{Spec} K$ is reduced but not geometrically reduced as $\operatorname{Spec} K \times_k \operatorname{Spec} K = \operatorname{Spec}(K \otimes_k K)$ and $K \otimes_k K$ has the nonzero nilpotent $x = 1 \otimes T^{1/p} - T^{1/p} \otimes 1$ with $x^p = 0$. Similarly, $X = \operatorname{Spec} \mathbb{R}[x]/(x^2 + 1) \simeq \operatorname{Spec} \mathbb{C}$ is irreducible (it is a single point) but not geometrically irreducible as $X_{\mathbb{C}} = \operatorname{Spec} \mathbb{C}[x]/(x^2 + 1) = \operatorname{Spec}(\mathbb{C} \oplus \mathbb{C}) = \operatorname{Spec} \mathbb{C} \sqcup \operatorname{Spec} \mathbb{C}$. \square
